TO  
THE UNITED STATES BUREAU OF  
LABOR STATISTICS

## PREFACE

THE figures which constitute the basis for the statistical analysis presented in these pages were collected for the United States Bureau of Labor Statistics by the authors and other members of the Bureau's staff. A large part of the material thus collected already has been utilized in various articles published in the Bureau's *Monthly Labor Review*. The Bureau of Labor Statistics, however, is responsible neither for the opinions herein expressed by the authors nor for the statistical treatment its original figures have received at their hands.

The authors desire to express their appreciation of the help they have received from Dr. Royal Meeker, formerly Commissioner of Labor Statistics and now editor of the *International Labour Review*, and from Mr. Lucian W. Chaney, of the staff of the Bureau of Labor Statistics. Mr. Ethelbert Stewart, now Commissioner of Labor Statistics, was in general charge of the field work of the Bureau's investigation of labor turnover. Working with the authors under his direction were Messrs. Boris Emmet, William F. Kirk, and Irving Winslow. To them and to Mr. Stewart the authors are very much indebted and they wish to take this opportunity to express their appreciation. Although they are too numerous to mention by name, the authors desire to express their deep sense of obligation to the hundreds of employment managers, factory superintendents, and business executives who cheerfully put themselves to great inconvenience in order to furnish the necessary information. The authors earnestly hope that this analysis of the figures they so kindly furnished may be of use to some of them.

To the Academy of Political Science at Columbia University, the Ronald Press Company, and the University of Chicago Press, the authors desire to extend thanks for permission to reprint material originally published in the *Political Science Quarterly*, *Administration*, and the *Journal of Political Economy*.

# CONTENTS

| CHAPTER  | PAGE  |
|--|-------|
| I. INTRODUCTION . . . . .  | 1-6   |
| 1. Nature and significance of labor mobility.  |       |
| 2. Scope and limitations of the basic data.  |       |
| II. DEFINITION AND MEASUREMENT OF LABOR MOBILITY   | 7-28  |
| 1. The base in "turnover" computation.   |       |
| (a) The pay roll as base.  |       |
| (b) Average daily work force   |       |
| (c) Labor hours.   |       |
| 2. Labor change rates.   |       |
| 3. The definition of terms.  |       |
| (a) The variables.   |       |
| (b) The base or standard of measurement.   |       |
| 4. The method of computation.  |       |
| 5. Relation between different methods of computation.  |       |
| III. PERSONNEL POLICY AND LABOR STABILITY . . . . .  | 29-33 |
| IV. GENERAL EXTENT OF LABOR MOBILITY . . . . .   | 34-60 |
| 1. Labor mobility and industrial conditions.   |       |
| 2. Extent of mobility in the 10-year period ending Dec. 31, 1919.                            |       |
| 3. Probable amount of labor shifting in the United States.                                   |       |
| 4. Necessary and unnecessary labor changes.  |       |
| 5. Labor mobility in certain localities.   |       |
| 6. Labor mobility in different industry groups.  |       |
| 7. Relation between size of establishment and labor mobility.                                |       |
| 8. Analysis of accessions.   |       |
| V. LABOR MOBILITY IN INDIVIDUAL PLANTS AND IN SPECIAL GROUPS WITHIN THE WORK FORCE . . . . . | 61-77 |
| 1. Labor mobility in individual establishments.  |       |
| 2. Mobility of male and female employees.  |       |
| 3. Day and night force.  |       |
| 4. Skilled and unskilled employees.  |       |
| 5. Occupational incidence of labor mobility.   |       |

| CHAPTER   | PAGE    |
|---|---------|
| VI. TYPES OF SEPARATION AND CAUSES OF TURNOVER  | 78-102  |
| 1. Types of separation.   |         |
| 2. Industry groups and type of separation.  |         |
| 3. Relation between skill and type of separation.   |         |
| 4. Type of separation and size of establishment.  |         |
| 5. Some causes for instability.   |         |
| VII. SEASONAL INFLUENCES ON LABOR SHIFTING . . .  | 103-114 |
| 1. Seasonal fluctuations in individual establishments.  |         |
| 2. Seasonal changes in different occupations.   |         |
| 3. Normal seasonal changes in stability.  |         |
| VIII. LENGTH OF SERVICE AS A FACTOR IN LABOR MOBILITY   | 115-141 |
| 1. Job tenure in different industry groups.   |         |
| 2. Comparative service stability of males and females.  |         |
| 3. Length of service of skilled and unskilled employees.  |         |
| 4. Length of service of casual laborers.  |         |
| 5. Length of service in different plant departments.  |         |
| 6. Average weekly service rates.  |         |
| 7. Length of service and type of separation.  |         |
| IX. STABLE AND UNSTABLE EMPLOYEES . . . . .   | 142-153 |
| 1. "Active employees" with service records of less than one year (unstable employees) and over one year (stable employees). |         |
| 2. Responsibility for labor mobility of the unstable employees.   |         |
| 3. The labor flux of unstable working forces in individual establishments.  |         |
| 4. Labor mobility of the unstable work force compared with the total work force.  |         |
| X. RELATIVE RESPONSIBILITY FOR* INSTABILITY OF DIFFERENT LENGTH OF SERVICE GROUPS . . . .                                   | 154-1   |
| 1. Analysis based on allocation of labor hours to length of service groups.   |         |
| 2. Frequency of job replacement in different length of service groups.  |         |
| XI. EMPLOYMENT RECORDS . . . . .  | 163-1   |
| 1. Labor mobility records.  |         |
| 2. Records of labor absenteeism.  |         |
| APPENDIX. BASIC TABLES . . . . .  | 172-211 |
| INDEX . . . . .   | 213-215 |

## INDEX OF TABLES

| CHAPTER II. THE DEFINITION AND MEASUREMENT OF<br>LABOR MOBILITY                               |   | PAGE  |

## LABOR TURNOVER IN INDUSTRY

# LABOR TURNOVER IN INDUSTRY

## CHAPTER I. INTRODUCTION

### NATURE AND SIGNIFICANCE OF LABOR MOBILITY

THE difficulty of maintaining a stable work force in industrial establishments has directed attention to the problem of labor instability, — a phenomenon observable in a particularly intensified form in times of prosperity, but found in only slightly less serious form even in periods of depression. Labor instability is regarded by all those who have given any serious consideration to the problem as one of the maladjustments of our industrial life, wasteful and destructive of the potential man-power of the nation, and a serious obstacle to the complete utilization of the country's productive forces. In tackling this problem it should be recognized at the outset that within certain limits establishment labor mobility is a normal and necessary thing. A certain amount of shifting from shop to shop and city to city is quite normal and even desirable; part of this necessary movement of labor is an entirely natural ebb and flow resulting from the normal expansion and contraction of industrial activity. Interest in the question of labor mobility is centered, therefore, not only upon its general extent but more specifically upon whatever part of it may be considered abnormal and unnecessary. When it is considered from this standpoint it is essential to know (1) the nature and extent of labor instability, (2) the various factors which are likely to increase or diminish its volume, and (3) whether any employment methods have been or can be devised which will make it possible to reduce labor instability to such an extent that maximum production may be attained at minimum cost and to the mutual advantage of employer and employee.

In order to give really adequate consideration to the various problems involved in labor instability as it affects different industries in the United States, and more particularly to devise methods for its reduction, it will be necessary to have more detailed and extensive data than hitherto have been available. Fortunately, during the last decade a number of progressive firms have given rather close study to the whole problem of labor instability. These concerns have made extensive experiments in labor management with a view to stabilizing the work force and have achieved a measure of success. It is these firms, especially, that have accumulated records sufficiently extensive to show both the magnitude and the intricacies of the problem. These records, moreover, will permit of a test of the effectiveness of certain labor policies and methods of employment. It is upon data from such establishments that this study is very largely based.

Labor instability is generally the consequence of (1) seasonal, cyclical, and other fluctuations in industrial activity which result in varying amounts of employment available to the job seeker; (2) individual or collective dissatisfaction with the conditions of employment; and (3) the dissatisfaction of employers with the services of some employees. In its relation to employer and employee this problem of labor instability becomes a more or less personal one and presents itself essentially in two aspects, depending upon whether it is the employee or employer who is concerned. (1) To the individual workman job changing may mean either gain or loss. In prosperous times, when there are more numerous and attractive job opportunities, the change of jobs may represent an actual gain to the worker. Even if there is nothing gained, it could scarcely involve a loss, because in a rising labor market jobs are likely to be actually awaiting the separating employee, and even at the worst, the period of unemployment between jobs is likely to be relatively short. In periods of depression the establishment labor mobility problem is, for the individual employee, a problem of unemployment and irregular

employment, the employee becoming the unwilling sufferer from the instability and less commonly the willing cause of it. (2) The individual employer, however, is chiefly interested in the maintenance of a stable working force and regards excessively numerous terminations of employment and, especially, voluntary and more or less avoidable separations as a serious obstacle to efficient and continuous operation. He is also very much concerned with the enormous expense to which he is put because of the excessive labor replacement (or, to use a phrase which has gained currency in industrial circles,— the labor turnover) required for the maintenance of his normal work force.

In the following pages the problem of labor instability is considered primarily from the standpoint of the individual establishment. This is done, not because labor mobility from the individual workman's standpoint is less deserving of consideration, but solely because, as has been explained, the data necessary to the study of this subject were readily available only from the records of those establishments which have made serious attempts to cope with the problem of instability. Looked at from the standpoint of the individual employer it becomes a matter of the first importance to consider the question: How are we to know when an establishment's labor instability becomes excessive? In other words, how are we to know where to draw the line between abnormal and avoidable labor changes and those changes which are due to purely external causes inherent in the industrial situation, — causes over which the employer cannot exercise any effective control? Labor instability may be regarded as excessive and as pointing to maladjustment or mismanagement when its volume is in any considerable excess over its volume in the more progressive concerns which have considerably reduced it, and more especially when its volume is in excess of that common to its particular industry in the same locality at any given time. Conversely, those firms which have a considerably higher stability record than commonly prevails in the industry are generally those which have successfully worked out certain

definite labor and employment policies, as is indicated by figures presented in a later chapter.

As already intimated, a degree of instability which is common and perhaps quite normal and necessary for one industry would be excessive for another. However, if two establishments in the same locality, of about equal size, employing about the same type of worker and engaged in turning out the same product, differ widely in the extent of their labor instability during identical periods of time, this difference usually indicates that the concern whose labor turnover is normal or more nearly normal is either pursuing a more advanced labor policy or that labor conditions (wages, hours, living conditions, etc.) are better than at the other establishment, or even that the more unstable plant is less favorably situated in respect to both of these particulars. Excessive labor instability, in other words, is very likely to be the result of labor mismanagement, low wages, insanitary working conditions, inferior or inadequate housing and transportation facilities, etc., or, what amounts to the same thing, it is the result of the heavy loss of employees to competitors whose labor policies are more enlightened, who pay higher wages, and who provide more attractive working conditions. The frequency of the labor changes, then, is a valuable index to the extent of labor unrest in an industrial establishment and a valuable measure of the effectiveness of the establishment's labor and employment policy.

#### SCOPE AND LIMITATIONS OF THE BASIC DATA

The statistical matter presented in the following pages is based primarily upon information secured by the authors and other representatives of the United States Bureau of Labor Statistics in the course of two extensive field investigations of the subject. The first of these was a pre-war inquiry made in 1915 and 1916 and reporting in a general way the extent of the turnover during the five-year period 1910-1915, and in more detail for the years 1913 and 1914 both the extent of it and the efforts made to reduce it. The second was a war-time investigation made in 1918,

and resulting in an intensive report on the labor mobility situation for the year ending May 31, 1918. By the use of material secured by correspondence some of the data from these field investigations have been brought down to the end of 1919. Returns from the two inquiries cover upwards of 260 establishments employing over 500,000 workers in seventeen of the most important industrial States.<sup>1</sup>

It is not claimed that the figures presented are necessarily and in all cases representative of American industry as a whole. It is realized that because of the relatively small number of establishments used in this study the various mobility rates shown must be regarded as being merely indicative of the general

<sup>1</sup> The following special articles, dealing with the labor turnover situation in different cities and in particular plants and industry groups as revealed in these investigations, have been published by the Bureau of Labor Statistics in the *Monthly Labor Review*:

- Brissenden, P. F.* "Labor turnover in the San Francisco Bay region" (February, 1919).
- "Labor policies and labor turnover in the California oil-refining industry" (April, 1919).
- "Labor turnover among employees of a California copper mining and smelting company" (May, 1919).
- "Employment policy and labor stability in a Pacific Coast department store" (November, 1919).
- "Employment policies and labor mobility in a California sugar refinery" (December, 1919).
- *and Frankel, Emil.* "The mobility of labor in American industries" (June, 1920). An official summary of the results of the Bureau's labor turnover investigations.
- Emmet, Boris.* "Labor survey of the Cleveland cloak industry" (August, 1918). On labor turnover and length of service, pp. 225-228.
- "Labor turnover and employment policies of a large motor-vehicle manufacturing establishment" (October, 1918).
- "Labor turnover in Cleveland and Detroit" (January, 1918).
- Frankel, Emil.* "Freight handlers on passenger-freight steamers on the Great Lakes" (April, 1918).
- "Labor turnover of seamen on the Great Lakes" (June, 1918).

turnover situation at any given time. But whatever may be the limitations of the figures for the measurement of the amount of labor mobility at any particular time, it is believed that they may be used with entire confidence in gauging the trend in mobility from season to season and from year to year.

## CHAPTER II

### THE DEFINITION AND MEASUREMENT OF LABOR MOBILITY<sup>1</sup>

ANY adequate comparison of establishment experience in dealing with labor instability as well as any clear presentation of the relative extent of that instability in different plants make a uniform use of terms and a uniform standard of measurement absolutely necessary. The complex problem of labor instability cannot adequately be discussed or clearly presented by use of a phrase of such necessarily narrow and specialized connotation as "labor turnover," which has, hitherto, been loosely used in reference to establishment labor instability generally. The use of the word "turnover" in any exact sense necessitates the assignment to that word of a precise and definite meaning. This has, so far, never been done. Indeed, the different ways in which the phrase "labor turnover" is interpreted and applied are distressingly numerous. The phrase should obviously be identified with whichever one of the current interpretations appears to have the greatest practical utility. On these grounds it would seem that the term "labor turnover" ought to be used in one sense, and one only, and that strictly in reference to the extent of shift and replacement necessary for the maintenance of the work force. This aspect of the matter is the one with which employers of labor are most intimately concerned. For use in reference to the larger aspect of the flow of labor into and out of industrial establishments, of which labor turnover or labor replacement is only one phase, a more inclusive term needs to be used. It seems that the phrase "labor mobility" best serves this more general purpose and it is accordingly so used in these

<sup>1</sup> Parts of this chapter originally appeared in somewhat different form in an article on "The Measurement of Labor Mobility," 28 *Journ. Polit. Econ.* 441-476 (June, 1920).

pages. This book is given the title "Labor Turnover" because it deals chiefly with the shifting and replacement involved in force maintenance, and because, on the whole, that expression seems less unsatisfactory than "labor replacement."<sup>1</sup>

#### ACCESSIONS, SEPARATIONS AND REPLACEMENTS

To make it easier to understand the method of measuring labor change in this study, it may be well to clear the ground by briefly referring to three aspects of labor mobility with which the phrase "labor turnover" has been hitherto closely identified. These are: (1) the number of employees hired (accessions), (2) the number leaving (separations), and (3) the number of replacements<sup>2</sup> required to keep up the work force. The United States Bureau of Labor Statistics originally used the replacements as "turnover."<sup>3</sup> Later on it identified separations with "turnover" and followed that method for a time.<sup>4</sup> Among private organizations each of the three concepts has its advocates. It is evident that neither accessions, separations, nor replacements when used alone completely interprets the whole labor mobility situation, nor can they when used alone adequately take into account the constantly varying factors inherent in the industrial situation.

<sup>1</sup> Other expressions roughly synonymous with "labor mobility" are "labor change" and "labor shifting." (See p. 12.)

<sup>2</sup> That is to say, the number of separating employees who have to be (and actually are) replaced.

<sup>3</sup> *Street-railway employment in the United States*, Bureau of Labor Statistics *Bulletin* 204, pp. 193-203.

<sup>4</sup> See articles on labor turnover in the *Monthly Labor Review* for October, 1918, and January, February, and March, 1919. The separations method is the one which has been used most commonly. It has been authoritatively expressed in the formula adopted by the National Association of Employment Managers, which later changed its name to the Industrial Relations Association of America, and which has now become the National Personnel Association. (Standard definition of labor turnover and method of computing percentage "labor turnover" formulated by a special committee at the Rochester Conference of Employment Managers, Rochester, N. Y., May, 1918. This "standard definition" is given in full in the *Monthly Labor Review* of the U. S. Bureau of Labor Statistics for June, 1918, pp. 172-173.)

## THE BASE IN "TURNOVER" COMPUTATION

In regard to the base upon which the amount of labor instability is to be computed the situation also leaves much to be desired. The number-on-pay-roll basis which has been most commonly used is patently defective because of the varying numbers of "dead" employees included, that is, employees, absent at first, who eventually separate from service but who are likely to be carried on the pay roll for varying periods of time after they have ceased to be active employees. The Bureau of Labor Statistics, in its first investigation, took the average of the weekly, fortnightly, or monthly numbers on the pay roll as representing the standard working force. This is a padded "standard," as will soon be made evident. The Rochester Conference proposed that the average number actually working from day to day be considered the "standard" working force. This, it is believed, comes nearer to a genuine standard base than any other proposal theretofore advanced. The trouble with both these methods is that they are not standards at all in any proper sense of the word. They may, indeed, constitute a fairly accurate base for determining the rate of labor flow in any particular establishment, but they do not constitute a common base for different establishments.

*The Pay Roll as Base.* — The statistical evidence available indicates quite conclusively that the average pay-roll number is an inflated and inconstant standard, and therefore a very inaccurate base for use in measuring labor mobility. Some appreciation of the amount of this inflation, due to dead and broken-time names on the pay roll, may be had from an examination of the records of a few establishments which kept their records in such a way that it was possible to compare the actual amount of employment as measured by the labor hours worked with the apparent amount of employment shown by pay-roll figures — which latter figures, of course, show the aggregate number who had been in service for any length of time during the pay period.

In Table 1 there are shown for five establishments the number of equivalent full-time workers for a given period of time and the average number of employees on the pay roll for the same period.

TABLE 1  
DIFFERENCE BETWEEN PAY-ROLL NUMBERS AND NUMBER OF EQUIVALENT  
FULL-TIME WORKERS

| CHARACTER OF ESTABLISHMENT          | AGGREGATE NUMBER OF ONE-MAN DAYS WORKED | NUMBER OF FULL-TIME WORKERS | AVERAGE NUMBER OF EMPLOYEES ON PAY ROLL | PER CENT EXCESS OF PAY-ROLL NUMBER OVER EQUIVALENT NUMBER OF FULL-TIME WORKERS |
|-------------------------------------|---|-----------------------------|---|--|
| Copper mine <sup>1</sup> . . .      | 82,016                                  | 247                         | 298                                     | 21   |
| Smelter <sup>1</sup> . . . . .      | 130,467                                 | 391                         | 506                                     | 29   |
| Electro-zinc plant <sup>1</sup> . . | 45,949                                  | 138                         | 185                                     | 34   |
| Machine Tool Mfg. <sup>2</sup> . .  | <sup>3</sup>                            | 3,855 <sup>4</sup>          | 4,046                                   | 5  |
| Metal Products Mfg. <sup>5</sup> .  | <sup>3</sup>                            | 1,047 <sup>4</sup>          | 1,151                                   | 10   |

Obviously, the margin of excess of the pay-roll number over the number of equivalent full-time workers indicates the extent to which the pay-roll records are "loaded" with names of employees who may have worked only a day or two of the pay period and who, therefore, do not represent employment — but merely a more or less padded pay roll. The use of the pay-roll number, even though it exaggerates the amount of employment (which is the true basis of computation), might still do fairly well as a base in computing mobility if only the margin of inflation were fairly uniform. Unfortunately it is not at all uniform. There are at once apparent wide variations between different plants, the least exaggeration of pay roll appearing in the machine tool manufacturing plant where the excess is only 5 per cent and the greatest in the electro-zinc plant where the excess is 34 per cent. The fluctuations in this margin of inflation are even wider between different pay-roll periods in the same establishments.

<sup>1</sup> Year ending May 31, 1918.

<sup>2</sup> Year ending June 30, 1915.

<sup>3</sup> No report

<sup>4</sup> Average daily work force.

<sup>5</sup> Calendar year 1915.

Thus, in the smelting plant shown in the above table the margin of pay-roll inflation ranges from 7 per cent in February to 52 per cent in April. These figures indicate that the true active working complement is unquestionably considerably smaller than the apparent complement indicated on the face of the pay-roll records. This margin is due to the counting of the names of those employees who served only a part of the pay period but whose names, nevertheless, were not dropped from the pay roll until after the end of the pay period. It is obvious that the pay-roll figures must be discounted for this "broken-time" margin. The necessity for making such a discount of the pay-roll figures forces the conclusion that the true base in labor mobility rate calculation must be expressed in some standard unit, say, 3000 hours — time roughly equivalent to the time put in by one employee working one year.

*Average Daily Work Force.* — A base subsequently recommended and one which more clearly approaches a true standard is the average daily work force, based upon attendance records. But it was found that even the use of the average daily working force as a base was hardly adequate for comparative purposes because the widely varying length of the work-day in different establishments, industries, and cities makes such figures inadequate. The average daily attendance plan was proposed very largely because it approximates more closely the average number of full-year workers. Since the amount of "turnover" is measured by the ratio between the number of replacements made and the average number of workers who are continuously employed throughout the period, it is evident that the requisite standard is to be arrived at by somehow pruning down the pay-roll figures to the equivalent number of full-year workers, as defined above.

*Labor Hours.* — It is suggested that this pruning can be done very effectively and in a way most conducive to standardization by using as an ultimate base the actual number of hours (or, failing a record of labor hours, the number of days) put in during the period considered.

## LABOR CHANGE RATES

Just as "turnover" is a misleading term for use in general reference to the phenomenon of labor instability, so the term "percentage" is equally confusing for use in measuring the extent of this phenomenon. We know exactly the extent of the replacement necessary to maintain the normal work force when we know, let us say, that replacements took place in any given concern at the rate of 2 for each full-year worker in the normal work force. In other words, the phrase "rate of replacement" accurately designates what "percentage of turnover" has been loosely used to express.<sup>1</sup>

Other items in the labor flow, and, indeed, its whole volume or flux, may be "rated" in a similar fashion. The rate at which employees leave may be called the separation rate, and the rate at which they are hired, the accession rate. Whichever of these two rates is the lower may, for all practical purposes, be used as the replacement rate. When the accession rate exceeds the separation rate, the difference between the two measures the labor increase rate. When the separation rate exceeds the accession rate, their difference measures the labor decrease rate. If the separation and accession rates are equal, either one may, of course, be used as the replacement rate and there is naturally neither increase or decrease, the concern in question being neither expanding nor curtailing operations. The rates of increase and decrease may be considered as marginal rates in relation to the replacement rates, the increase rate measuring the amount, if any, of inflow over and above replacement inflow and the decrease rate measuring the amount, if any, of outflow over and above the outflow which has to be (and sooner or later is) replaced. The

<sup>1</sup> The phrase "percentage of turnover" has also been used to express "the ratio of the total number of separations . . . to the average number of employees on the force report." — *Standard definition of labor turnover and method of computing the percentage of labor turnover*, National Conference of Employment Managers, Rochester, New York, May 9 to 11, 1918, 6 *Monthly Labor Review*, 1534-1535 (June, 1918).

accession rate plus the separation rate gives the total rate of labor change—a single rate of labor flux on the basis of which the mobility of labor in one occupation, shop, industry, or locality may be compared with its mobility in any other occupation, shop, industry, or locality. These different types of labor mobility or labor change rates may be classified as follows:

1. Accession rate (or hiring rate)
2. Separation rate  $\left\{ \begin{array}{l} \text{quitting rate (leaving voluntarily)} \\ \text{discharge rate ("firing" rate)} \\ \text{lay-off rate} \end{array} \right.$
3. Replacement rate (separations minus excess of separations over accessions). This is the "turn-over" rate.
4. Labor increase rate (accession rate minus separation rate)
5. Labor decrease rate (separation rate minus accession rate)
6. Flux rate (accession rate plus separation rate)<sup>1</sup>

If there is no excess of separations over accessions, that is to say, if the separations exactly equal, or are exceeded by, the accessions, the number of separations, as it stands, represents the number of replacements. It is evident, then, that whichever number—accession or separation—is the smaller must represent the number of replacements. It should be very carefully observed, however, that serious error may result when the attempt is made in this fashion directly to deduce the number of replacements from the accession and separation figures when these figures represent the aggregate of several establishments or even in some cases, of several groups (departmental, occupational, etc.) within a single establishment. Thus, for example, in Table 7 it is evident that the 86,179 separations which took place in the 16 plants in 1910, although, as compared with the 90,408 accessions, they would come much nearer to the number

<sup>1</sup> The use of the expressions "labor flux," "labor increase," and "labor decrease" has been suggested to the writers by Lucian W. Chaney, of the United States Bureau of Labor Statistics. Mr. Chaney has also suggested the term "industrial rates" for use in general reference to labor mobility rates, accident rates, etc. The authors wish to take this opportunity to express their indebtedness to Mr. Chaney in the whole subject-matter of this chapter.

of replacements, are in all probability considerably above it, since it is likely that in some of the 16 establishments the separations exceeded the accessions—in other words, contained non-replacement changes. The only method of obtaining absolute accuracy in regard to replacements is to segregate in a separate column the replacement numbers (whichever is smaller, accessions or separations) for each labor group (whether occupation, department, sex, plant, or locality) for which figures are shown, add the replacement numbers for each group, and figure the replacement rate independently on the basis of the total thus obtained. It is evident, of course, that in such a case as that of Table 3, where the work force of a single plant is taken as a unit, the replacement rates may be directly deduced as indicated in the formula.

The marginal flow, mentioned above, made up of excess hirings or excess separations, as the case may be, is not without importance. It is not labor replacement, however. Its importance, so far as force maintenance is concerned, is quite secondary. As a contributing or causal factor in unemployment in general, it is of vital importance both to the employing firm and to the community. Consider, for the moment, not merely the labor replacement involved in the establishment's force maintenance, but its labor mobility situation as a whole. As already noted, this total stability situation is best represented by the sum of the accession and separation rates. This includes not only the accessions and separations which are replaced (and which form the basis of the replacement rate), but also any possible marginal flow (of excess recruits or "quitters"<sup>1</sup>) expressed in the form of labor increase or decrease rates, as the case may be. This total establishment flow, as already intimated, is perhaps the best single index to the general labor stability situation in any establishment and to its standing as compared with other establishments. This total flux figure is quite readily ascertainable and it can easily be computed.

<sup>1</sup> The word "quitters" is used in these pages in the sense of "terminating" and refers to all employees leaving service, for whatever reason.

From the standpoint of the employee, labor mobility means irregular employment and unemployment. In the present work we are not primarily concerned with unemployment as a community problem or as a personal employee problem; we are concerned with it simply as an establishment problem. The primary purpose of this analysis is to gauge the labor flow into and out of the factory, including that part of the labor flow which (necessarily or unnecessarily) is involved in the maintenance of the normal work force — the phase of labor mobility here referred to as “labor replacement,” “or labor turnover.” These terms express the employers’ professional interest in unemployment as a phenomenon of the labor flow — into and out of his establishment. Quite naturally, he is more concerned about the number of men it is necessary to hire to keep the establishment going than he is about the number of days unemployed individuals may be out of work each year.

#### SUGGESTED CHANGES IN COMPUTATION PRACTICE

It is here proposed to make certain definite changes in computation practice in regard to all the factors entering into the measurement of the labor flow:

1. As to the relatively more variable factor — the ebb and flow of industrial labor — it is suggested that it be measured by (a) making use of accessions as well as separations, (b) from the relation between these two more or less accurately gauging the replacements, and (c) adding accessions to separations, thus showing the labor flux.

2. As to the relatively constant factor, or base — the normal or standard working force — it is proposed to use, instead of the average number on the pay roll, the number of 3000-hour (or 300-ten-hour-day) workers to which the total hours (or days) put in during the period are calculated to be equivalent.<sup>1</sup> This

<sup>1</sup> The 3000-hour basic year is a more or less arbitrary standard amount of employment, taken as being roughly equivalent to the amount of labor time normally put in by the average fully employed industrial employee. It is not meant to discount the very real advantages of the eight-hour day.

TABLE 2

<sup>1</sup> Establishments numbered below 100 are those reported in the pre-war inquiry; those numbered above 100 were covered in the later investigation. Concerns carrying a double number, therefore, appeared in both investigations.

<sup>2</sup> The replacement rates are marked with an asterisk.

# DEFINITION AND MEASUREMENT

<sup>1</sup> The replacement rates are marked with an asterisk.

number may be derived from the labor-time records or, failing such records, the daily attendance records or wages and salary-account records, as explained in another section of this chapter. This standard base will be called for convenience "the equivalent full-year worker" or, more briefly, "the full-year worker."

3. It is then proposed, in place of the rate of gross separation per 100 in attendance or the rate of gross accession per 100 on the pay roll (both so-called "turnover percentages"), to use as a double index of the shifting involved in labor maintenance and of the extent, as well, of labor increase and labor curtailment, the rates of accession and separation per equivalent full-year worker, and as an index to the general stability situation the total labor flux rate per full-year worker, the "full-year worker" being a standard unit, the number of which is obtained by dividing the total number of hours (or days) worked during the period considered by the 3000 hours (or 300 days) of a standard working year. The rate is arrived at by dividing the number of labor changes (of whatever kind) by the number of "full-year workers." As will be explained in another part of this chapter, not only these accession and separation rates, but the labor replacement, labor increase, labor decrease, and total labor flux rates each can be computed separately and their general trend and relations to each other readily charted in graphic form.

The whole significance of the use of replacements rather than gross separations as an index of labor flux, as well as the relation between the accession, separation, and replacement rates, is best brought out by the use of data showing the average number of employees and the number hired and leaving by months over a fairly long period. This will give some notion as to the trend of accessions, separations, and replacements. Such illustrative data are contained in Table 2.

The figures presented are from a metal products manufacturing establishment in the Middle West. They show for the twelve-

CHART A. TREND OF LABOR MOBILITY RATES IN A METAL-PRODUCTS MANUFACTURING PLANT, FROM JANUARY, 1911, TO APRIL, 1919

(Units: One labor change per full-year worker; One thousand employees; Logarithmic scale of ordinates)

month periods indicated the rates of labor change (flux, accession, and classified separation) per full-year worker. They are, in other words, "smoothed" rates derived (by the method of moving averages) from the actual rates for each month, which latter in turn are computed by dividing the actual number of labor changes of each particular kind that occurred during each month (the variable) by the number of full-year workers<sup>1</sup> employed during that month (the base). Thus, e.g., the figure 2.20 at the top of the accessions column is the accession rate for the twelve-month period ending December 31, 1912, and the figure 2.28 is the rate for the twelve-month period ending January 31, 1913, etc. Replacement rates among total separations and accessions are indicated by asterisks.

The moving annual labor change rates given in Table 2 for the overlapping twelve-month periods are, with the exception of the classified separation rates, shown graphically in Chart A.<sup>2</sup>

The two curves marked "accessions" and "separations" tell the whole story. There are obviously two main movements. There was a distinct downward movement — a movement toward greater stability — during the greater part of the four-year period, 1912-1915. The following four years — the years of the World War — witnessed a movement, quite precipitate at first, toward greater mobility. The accession and separation rates follow a roughly parallel course during the seven-year period. The average number of employees underwent a slight increase. The flux rate curve shows a form roughly corresponding, of course, to the trend of accessions and separations. It was 4.10 per full-year worker in 1912, 1.91 in 1915, and 6.39 in 1919. The replacement curve (marking the trend of the starred figures in Table 2) is shown on the chart by a line drawn parallel to a line

<sup>1</sup> That is to say, 3000-hour workers, as explained above.

<sup>2</sup> The chart was drawn by Mr. Leon Kirsch, formerly of the United States Bureau of Labor Statistics. Both the chart and Table 2 are reprinted by permission, from an article on "The Measurement of Labor Mobility," by P. F. Brissenden, 28 *Journal of Political Economy*, 454-455, 457 (June, 1920). The classified separation rates are plotted on Chart E on page 83.

connecting the lower points in the lines showing accessions and separations. It is evident that at the beginning of the period accessions were in excess, so that separations measured replacements, whereas at the end of the period the reverse relation held true and accessions consequently measured replacements.

In 1912 employees in this particular factory were being replaced at the rate of 1.90, in 1915 at the rate of 0.91, and in 1919 at the rate of 3.01 per full-year worker. Either the replacement curve or the flux curve would seem to serve quite well as single indices of the labor stability situation. The labor flux rate was cut down 54 per cent during the period from January 1, 1912, to December 31, 1915, but between the latter date and April 30, 1919, it underwent an increase of 235 per cent.

When the accessions are in excess of the separations, the factory is building up its force, and the extent to which they are in excess measures the amount of recruiting being done. When the separations, on the other hand, exceed the accessions, the factory must be cutting down its operations and reducing its force, and the margin by which the separations are in excess measures the amount of labor decrease. In the chart the dark shaded areas show the extent of labor increase and the light shaded areas the extent of labor decrease.

#### DEFINITION OF TERMS

The precise definitions of the different factors which have been discussed in the preceding pages may now be formulated and the method of computation described:

*The Variables.* — The whole phenomenon of the movement of labor into and out of industrial establishments is referred to here as "labor mobility."<sup>1</sup> Those hired are referred to as "accessions." Those leaving service, under whatever circumstances,

<sup>1</sup>The term "labor mobility" primarily connotes movement. From the employer's standpoint, however, it will sometimes be convenient to refer to it as instability, or even to use the word "stability" — where that word seems to be appropriate.

are referred to as "separations." Those of the accessions which are made to fill the vacancies made by separations are replacement accessions, or "replacements." Whichever one of the two items, accessions or separations, is the smaller may conveniently be taken as measuring the number of replacements. The total number of labor changes, that is to say, the sum of the accessions and separations, is the "labor flux." The amount by which the accessions in an expanding business are in excess of the separations is the amount of "labor increase." The amount by which the separations in a plant which is curtailing operations exceed the accessions is the amount of "labor decrease." Unless otherwise indicated in the context, the word "turnover," in this book, is used in reference to rate of replacement.<sup>1</sup>

*The Base or Standard of Measurement.* — As to the base or normal work force to which the number of labor changes, or the number of replacements, or accessions, etc., must be compared in order to show the frequency or rate of change, use is made of the aggregate number of hours actually worked by all employees for any period. This is a genuine standard base, inasmuch as it accurately represents the volume of employment, or the amount of industrial exposure. This base at once eliminates all inflation due to dead and broken-time names on the pay roll, thus putting establishments with varying amounts of employment on a par and making the strictest comparability possible.<sup>2</sup>

#### METHOD OF COMPUTATION

The exact method of measuring labor mobility used in this study is as follows: The general extent of labor mobility is statistically determined by comparing the total movement of

<sup>1</sup> The relations between accessions, separations, replacements, and flux may be seen from the tabular presentation of them all in Table 3. See above, p. 8, note 4.

<sup>2</sup> In the earlier studies of labor turnover made by the Bureau of Labor Statistics the average daily work force was first used as a base but was later changed to the full-year of 3000-hour worker. Finally, the Bureau decided to use the unit labor hour or some decimal multiple thereof. (10 *Mo. Lab. Rev.* 1344.)

labor in and out (accessions and separations) during any given period with the number of "fully-employed-worker" labor-time units of 3000 hours put in by the work force during that period. The number of labor changes, in other words, is compared with the number of full-year workers. This flux or total labor change rate is believed to constitute the best single index to the general stability situation in any plant or group of plants and in subdivisions within individual establishments. The flux rate is made up of the accession rate and the separation rate. The two latter rates should be shown separately in order to reveal the whole stability situation. The separation rate should be subdivided so as to show the relative responsibility for the labor outflow of discharges, lay-offs, and quits. The rate of replacement, which means the rate at which separating employees whose places must be filled are replaced by others, may be, for all practical purposes, defined as and identified with the rate of separation when that rate is lower than the accession rate and as the rate of accession when that rate is lower than the separation rate.<sup>1</sup> When the accession rate exceeds the separation rate, the difference between the two measures the labor increase rate. When the separation rate exceeds the accession rate, their difference measures the labor decrease rate. If the separation and accession rates are equal, either one may, of course, be used as the replacement rate and there is naturally neither increase nor decrease, the concern in question being neither expanding nor contracting. The rates of increase and decrease may be considered as marginal rates in relation to the replacement rates, the increase rate measuring the amount, if any, of inflow over and above replacement inflow and the decrease rate measuring the amount, if any, of outflow over and above the outflow which has to be (and sooner or later is) replaced.

The different mobility or labor-change rates are given in these pages as rates per full-year (or 3000-hour) worker. For illustration: The figures in Table 7 show that during the year ending

<sup>1</sup> See above, p. 13.

May 31, 1918, the sum total of accessions and separations for the 176 establishments reported was 1,244,640. The number of labor hours worked in these plants during this period was 917,703,000. Consequently the

*Flux rate* (per full-year worker) is . . . . .  $\frac{1,244,640}{917,703,000} \times 3,000 = 4.80$

the *Accession rate* . . . . .  $\frac{631,173}{917,703,000} \times 3,000 = 2.07$

the *Separation rate* . . . . .  $\frac{613,467}{917,703,000} \times 3,000 = 2.01$

The rates for any departmental, occupational, or other subdivision of the work force can be figured in exactly the same way. Thus, for example, to get the accession rate divide the number hired for the particular department or occupation during the period covered by the number of labor hours worked in that department or occupation group during the period and multiply by 3000. It at once will be evident that the same results can be obtained in more direct fashion by simply dividing the number of labor changes by the number of full-year workers.

The meaning of all of these different phases of labor mobility and their relation to each other are brought out in a somewhat clearer fashion in Table 3 (presented here merely to throw light on method and terminology), which shows for the years 1917 and 1918 the rate per full-year worker of flux, accession, separation, replacement, labor increase and decrease, in an automobile manufacturing plant.

It is evident from these figures that in 1917 to maintain a labor force of 35,401 workers, who put in 106,203,000 labor hours, there were 14,827 separations. Of these 6863 represented curtailment — labor decrease. They were either lay-offs, discharges or quits taken advantage of to reduce the force, and not replaced. To make good the remaining 7964 separations, 7964 new workers were hired. There were, then, in that year 22,791 labor changes involved in the maintenance and curtailment of a work force of 35,401 persons. In 1918 the plant under-

went expansion, its labor increase rate being .07 per full-year worker. There were 24,349 separations, all of which had to be replaced. In addition, plant extension required a labor increase of 2223, making a total of 26,572 accessions. There were altogether in 1918 no less than 50,921 labor changes required to maintain and enlarge a work force of 31,911 and to get 95,733,000 hours of work done. In other words, in 1917 the accession rate was .23 and in 1918 it was .83 per full-year worker; the separation rate was .42 and .76 in 1917 and 1918, respectively; the

| 1918 . . . | 1,340 <sup>2</sup>                    | 31,911                                | 50,921                                      | 20,572     | 24,349      | 24,349       | 2,223                  | —                      |
|            | RATE PER FULL-YEAR (3000-HOUR) WORKER |                                       |   |            |             |              |                        |                        |
| 1917 . . . | 0.05                                  | —                                     | 0.64  | 0.23       | 0.42        | 0.23         | —                      | 0.19                   |
| 1918 . . . | 0.04 <sup>2</sup>                     | —                                     | 1.60  | 0.83       | 0.76        | 0.76         | 0.07                   | —                      |

replacement rate .23 and .76; and the flux rate .64 and 1.60. In 1917 the establishment underwent curtailment at a rate of .19 (and in 1918 it underwent expansion at a rate of .07) per full-year worker. This means that when the accessions are in excess of the separations the factory is building up its force, and the extent to which they are in excess measures the amount of labor recruiting being done. When the separations, on the other hand, exceed the accessions, the factory evidently is cutting down its operations

<sup>1</sup> Taken by permission from article on "Measurement of labor mobility," 28 *Jour. Polit. Econ.* 444.

<sup>2</sup> Based on records for first six months only.

and reducing its force, and the margin by which the separations are in excess measures the amount of industrial demobilization going on in that factory.

#### RELATION BETWEEN DIFFERENT METHODS OF COMPUTATION

The relation between the two principal methods which have been used hitherto in labor turnover computation and the method followed in this book is shown in Table 4, in which the figures of methods II and III are derived from those of method I which are taken from Table 7. Separation rates in round numbers are given in parentheses:

TABLE 4  
COMPARISON OF THREE METHODS OF MEASURING LABOR MOBILITY

| PERIOD  | ACCESSION | SEPARATION | FLUX  |
|---|-----------|------------|-------|
| <b>I. RATE PER FULL YEAR (5,000 HOUR) WORKER</b>                                    |           |            |       |
| 1913-1914 . . . . .   | 03        | 99 (1)     | 1 02  |
| 1917-1918 . . . . .   | 2 07      | 2 01 (2)   | 4 08  |
| <b>II. RATE PER 10,000 LABOR HOURS</b>  |           |            |       |
| 1913-1914 . . . . .   | 3 07      | 3 27 (3 3) | 6 34  |
| 1917-1918 . . . . .   | 6 83      | 6 63 (6 6) | 13 46 |
| <b>III. "PERCENTAGE OF TURNOVER"<sup>1</sup><br/>(So-called "Rochester" Method)</b> |           |            |       |
| 1913-1914 . . . . .   | —         | 99 (100)   | —     |
| 1917-1918 . . . . .   | —         | 201 (200)  | —     |

A separation rate of 3.3 per 10,000 labor hours, as the Bureau of Labor Statistics now computes "turnover,"<sup>2</sup> or a separation rate (called, Rochester fashion, "percentage of turnover") of 100 per hundred on the work force, as the Bureau formerly figured "turnover," are both equivalent to a separation rate

<sup>1</sup> That is, the rate per 100 full-year workers (or employees on the pay roll).

<sup>2</sup> This is also the Bureau's official method of computing industrial accident rates. 10 *Monthly Labor Review*, 218-219 (January, 1920).

per full-year worker of 1.00 as used in these pages.<sup>1</sup> Conversely, a separation rate of 2.00 per full-year worker as used here is equivalent to a separation rate of 6.6 per 10,000 labor hours and to a "percentage of turnover" (Rochester formula) of 200. The flux rate on the new basis used here would be 2.00, which is the same as a flux rate of 6.6 per 10,000 labor hours. Such a rate indicates that during the period under observation the sum total of the number hired and leaving is equal to twice the number of full-year workers employed. When the accession and separation rates in any establishment each stand at or close to 1.00, thus giving a flux rate of 2.00, the situation in that plant is one equivalent to a complete overturn of the work force. But this complete work-force turnover flux rate of 2.00 may actually represent three distinctly different industrial situations, the revelation of which is one of the useful functions of accession and separation rates: (1) accessions 1.00, separation 1.00, a going concern which is neither expanding nor curtailing its operations; (2) accessions 1.50, separations .50, a concern which is undergoing more or less rapid extension of plant; and (3) accessions .50, separations 1.50, a concern which is curtailing activities. One or the other of these three different situations is involved in every rate of total labor change, whether it be in a very stable plant with a flux rate of 1.00 or a very unstable one with a flux rate of 4.00.

The fact should be emphasized that the primary object in gauging the extent of labor mobility is to ascertain the number of labor changes involved in the maintenance (and the necessary expansion or reduction) of the labor force. The number of different individuals involved in these changes is of less importance here than the number of repeated transactions. The computation method here used indicates the number of changes which take place, but it obviously involves double counting and does not, therefore, furnish a true report of the number of different persons

<sup>1</sup> The Bureau's rates (as published, e.g., in the *Monthly Labor Review* for June, 1920, pp. 36-56) may, therefore, be put upon a comparable footing with those given in this book by multiplying them by .3.

involved in the labor shiftings. The accession rate reported for a single concern is sure to include some employees who have been hired more than once during the period covered by the figures. The same is true of the separation rate and the flux rate. The figures for a group of establishments may also contain the accessions of certain employees whose separations are included, as they should be, in the separation figures for the same group. It is important to observe that this double counting does not affect the accuracy of figures designed to show merely repeated transactions. Moreover, since the concerns here reporting are widely scattered geographically and well distributed as to industry, there would not be likely to be many employees shifting from job to job within the group of firms reported. That is to say, when a worker left one of these plants the chances would be heavily against his being taken on by one of the other firms in this small group. But if he is so taken on, he is rightly to be counted twice, since he has made two labor changes.<sup>1</sup>

<sup>1</sup> For more detailed treatment of this widely discussed problem of the measurement of labor turnover see "Computing Labor Turnover: a Questionnaire," 56 *Industrial Management*, 239-246 (September, 1918); Doten, Carroll W., "Computing Labor Turnover," 56 *Industrial Management*, 339 (October, 1918); Emmet, Boris, "The Nature and Computation of Labor Turnover," 27 *Journal of Political Economy*, 105-116 (February, 1919); Crum, F. S., "How to Figure Labor Turnover," 16 *Quarterly Publications of the American Statistical Association*, 361-373 (June, 1919); Douglas, Paul H., "Note on Methods of Computing Labor Turnover," 9 *American Economic Review*, 402-405 (June, 1919); Slichter, S. H., "The Scope and Nature of the Labor Turnover Problem," 34 *Quarterly Journal of Economics*, 329-345 (February, 1920); and Brissenden, P. F., "The Measurement of Labor Mobility," 28 *Journal of Political Economy*, 441-476 (June, 1920).

## CHAPTER III

### PERSONNEL POLICY AND LABOR STABILITY<sup>1</sup>

A VERY effective illustration of the practical usefulness of labor mobility figures is furnished in a comparison of the mobility experience of ten selected establishments with that of all other establishments reporting. The labor flux rates in each of the ten selected plants are shown for the period 1913-1919 in Table 5. For convenience in making comparisons the corresponding flux rates for all establishments reporting are given in the last column.

A more complete exhibit of the two groups of concerns compared in Table 5 is given in Table 6, which places side by side for each year of the seven-year period the rates of accession, separation, and flux in (1) the ten selected establishments and (2) all establishments reporting. The labor flux rates of Table 6 are shown graphically in Chart B.

The ten concerns whose records are set forth in Tables 5 and 6 were chosen not only because they had definite labor policies and centralized employment machinery, but also on account of the fact that they had had considerable success in stabilizing their work forces and keeping their labor mobility rates down to relatively low levels. The figures demonstrate, so far as it is possible

<sup>1</sup>For a valuable discussion of different employment methods and their effect upon labor stability, see Sumner H. Slichter, *The Turnover of Factory Labor* (New York, 1919). See also Kelly, R. W., *Hiring the Worker* (New York, 1918) and Colvin, F. H., *Labor Turnover, Loyalty and Output* (New York, 1919). The following articles describe in detail the methods used in certain establishments which have successfully applied modern employment practices: "Labor Turnover and Employment Policies of a Large Motor-vehicle Manufacturing Establishment," by Boris Emmet, *Monthly Labor Review*, October, 1918; "Employment Policy and Labor Stability in a Pacific Coast Department Store" and "Employment Policies and Labor Mobility in a California Sugar Refinery," by P. F. Brisenden, *Monthly Labor Review*, November and December, 1919.

to demonstrate such things in statistical terms, the definite effectiveness of liberal labor policies and more or less centralized systems of employment. The curves of Chart B show in striking fashion that the ten selected establishments have brought about a considerable reduction in the extent of their labor shift and have suffered a much slighter decrease in stability during the war period than did the general run of establishments. It appears from the figures of Table 6 that for the whole period, 1913-1919, the 10 selected concerns had an average labor flux rate of 1.53 as compared with a rate of 2.25 for all other concerns. The selected plants reduced their flux rates from 3.27 in 1913 to 1.68 in 1919, but were forced up to 1.83 in 1918, which was the highest point reached after 1913. Establishments generally began with a rate of 2.61 in 1913, were pushed in 1918 up to 4.08 (over twice the mobility experienced by the selected concerns), and finished in 1919 with a rate of 2.10. This comparison of achievements, which covers a relatively long period, shows the vital importance from the standpoint of the industrial establishment of studying this subject of labor mobility, the necessity of examining the employment and personnel methods currently practiced by the more far-sighted employers, and the desirability of keeping systematic and continuous employment records in order to gauge the effect of labor policy upon labor stability. It demonstrates, as well, the urgent need for the more widespread adoption by employers generally of such labor and employment policies as will be most effective in eliminating from industrial life the evil and the waste of unnecessary hiring and firing.

Scientific employment, like high wages, in the long run is an economy. It is less expensive to keep trained, experienced men than it is to hire new and untrained ones. Policies of wholesale lay-off and indiscriminate discharge are very costly. In boom times or bad it pays to conserve human as well as material resources, to put just as much thought and technique into hiring and utilizing men as is given to the purchase and elaboration of raw materials.

CHART B. COMPARISON OF LABOR FLUX RATES PER FULL-YEAR WORKER IN TEN SELECTED ESTABLISHMENTS WITH CORRESPONDING RATES IN ALL OTHER ESTABLISHMENTS REPORTING, 1913-19.  
(Unit: One labor change per full-year worker; Logarithmic scale of ordinates.)

## CHAPTER IV

### GENERAL EXTENT OF LABOR MOBILITY

LABOR mobility, as already has been pointed out, varies with current industrial conditions, and changes in these conditions naturally influence the extent of the flow of labor into and out of our industrial plants. What effect these alternating periods of prosperity and depression have upon the extent of accessions and separations themselves, disregarding for the moment the particular kind of establishment or its location, may be briefly summarized somewhat as follows: In a rising labor market many new employment opportunities are created, which means that jobless workers get jobs and many employed workers leave their jobs and take employment elsewhere, ostensibly to better their industrial situation. Because of the urgency of the work it becomes necessary to replace quickly those employees who have left. The rapidity with which employees leave their jobs and the extent to which job changes take place will depend upon the extent to which industrial operations are enlarged and how favorable an employment situation is thus created. The more favorable the employment situation, the larger the number of accessions. These, of course, in addition to those hired from among the unemployed, are the cause of an increase in the number of separations from other plants, where, in turn, additional replacement accessions are required. Through the single fact that employees leave their jobs in rapid succession constantly increasing employment opportunities are created, thus increasing both accessions and separations.<sup>1</sup>

When there is extensive industrial activity and considerable

<sup>1</sup> The fact that labor turnover is heaviest in periods of prosperity partially explains the existence in such periods of the so-called "irreducible minimum of unemployment."

competition for labor, the process of selection in industrial establishments also considerably accelerates the frequency of labor shifting. It is obvious that when an establishment is rapidly increasing its work force in a tight labor market it cannot usually make a very careful examination of the fitness of a particular applicant for the job. During such times it is also possible that people are taken on who in normal times would not be hired at all. After these people actually begin to work in an establishment, however, a good many of them will be found to be unfit or undesirable and after a longer or shorter period of service are let go. This selective process is, of course, greatly intensified in times of unusual industrial activity, when there is a scarcity of labor. All this involves an increase in the number of both accessions and separations far above the ordinary number, which is already unnecessarily large.

In periods of industrial depression, when there are considerably fewer job opportunities relatively to the labor supply and the number of available job opportunities is diminishing, there will take place at first a considerable number of forced separations (lay-offs and discharges); there will be, moreover, fewer voluntary separations. There will be practically no occasion for accessions to build up force and much less need for accessions for replacement, inasmuch as most of the jobs abandoned are being at least temporarily discontinued. While under these circumstances the number of separations may at first be considerable, the whole number of separations over the entire period of depression and the sum total of labor changes during that period will on the whole be much less.

The enormous proportions that labor mobility may assume will be appreciated from an examination of Table 7.<sup>1</sup> In this

<sup>1</sup> Taken, after shifting the rates to the full-year-worker basis, from the writers' report on "The Mobility of Labor in American Industry," 10 *Mo. Labor Rev.* 1347 (June, 1920).

## LABOR 'TURNOVER IN INDUSTRY

TABLE 7

LABOR MOBILITY, BY YEARS, 1910-1919

[Replacement (or "turnover") numbers and rates are marked by asterisks (\*)]

| YEAR   | NUMBER OF ESTABLISHMENTS | NUMBER OF FULL-YEAR WORKERS <sup>1</sup> | TOTAL LABOR HOURS (THOUSANDS) | LABOR CHANGES |             |              |
|--|--------------------------|--|-------------------------------|---------------|-------------|--------------|
|  |                          |  |                               | ACCESSIONS    | SEPARATIONS | TOTAL (FLUX) |
|  |                          |  |                               |               |             |              |
| NUMBER   |                          |  |                               |               |             |              |
| 1910 . .   | 16                       | 85,263                                   | 255,789                       | 90,408        | 86,179*     | 176,587      |
| 1911 . .   | 24                       | 109,653                                  | 328,959                       | 94,020*       | 96,915      | 190,944      |
| 1912 . .   | 54                       | 188,303                                  | 565,089                       | 210,085       | 182,287*    | 392,372      |
| 1913 . .   | 113                      | 399,449                                  | 1,198,347                     | 541,740       | 535,118*    | 1,076,864    |
| 1913-14 <sup>2</sup> .                             | 84                       | 244,814                                  | 734,442                       | 227,008*      | 243,707     | 470,715      |
| 1914 . .   | 162                      | 373,287                                  | 1,110,861                     | 300,121*      | 326,755     | 626,876      |
| 1915 . .   | 51                       | 159,054                                  | 477,162                       | 122,211       | 99,734*     | 221,945      |
| 1916 . .   | 20                       | 94,803                                   | 284,400                       | 131,300       | 101,102*    | 232,402      |

<sup>1</sup> The figures in column headed "Number of full-year workers" in this and following tables in this book are obtained by dividing the total labor hours by 3000. These figures are given simply to indicate the approximate size of the work force to make it possible directly to compare the absolute number of labor changes with the number of employees in the work force.

<sup>2</sup> The figures given for 1913-14 and 1917-18 are from establishments reporting in great detail during the two field investigations of this subject made by the Bureau of Labor Statistics in 1915 and 1918. The time covered by the statistical data from these establishments is a 12-month period ending usually about the middle of 1914 and 1918, respectively. This applies to the material shown for these dates throughout this book.

<sup>3</sup> Computed, as already explained, by dividing number of labor changes by the total number of labor hours and multiplying by 3000. The same results, of course, will be obtained by dividing the labor-change numbers by the corresponding numbers of full-year workers.

table the combined figures for the years 1910 to 1919 show that in the establishments reporting the accomplishment of 6,353,046,000 hours of work, which is labor time equivalent to that of 2,117,682 full-year (3000-hour) workers, there were entailed 2,564,037 accessions and 2,481,280 separations, or a total of 5,045,317 labor changes. In other words, on the average, for each year of the decade 256,404 accessions, 248,128 separations, or a total of 504,532 labor changes were involved in the maintenance, and the necessary enlargement or curtailment, of a labor force of 211,768 workers. This means that the maintenance and necessary expansion or curtailment of the requisite work force involved labor changes considerably more than equivalent to a complete annual overturn of the work force. This is as if during one year all the employees had left their jobs and a complete new set of work people had taken their places. It appears then that each year on the average the number of persons who quit, were laid off, or discharged, as well as the number who had to be hired, was much larger than the total number of workers on the force at any one time.

The separation rate figures in Table 7 and almost invariably throughout the book are set in bold-face type.<sup>1</sup> An examination of these figures together with the accession and flux rates (bearing in mind the fact that a flux rate of 2.00 represents a complete overturn of the force) will show that in five of the ten calendar years represented the number of labor changes in the plants re-

<sup>1</sup>This is done, not so much because of any special importance attaching to separations as compared with accessions or flux, but in recognition of the wide prevalence of the conception of separations as turnover and the common habit among employers and employment managers of speaking of the "percentage of turnover" as signifying the number of separations per hundred employees. Since the rates per full-year worker, as computed in these pages, are so figured as to show two decimals, it at once will be evident that the separation rates may be read directly as "percentages of turnover" by the simple expedient of omitting the decimal point. Thus, in Table 7, a separation rate of 1.02 in 1910 is the same as a turnover percentage of 102. The same method of translation is just as feasible for those who, when they say "percentage of turnover," mean the number of replacements per hundred employees.

porting has been more than equivalent to a complete overturn of the work force; that is, there were at least as many accessions and at least as many separations as there were workers on the force. Even in 1915, the most stable year of the decade, there were 122,211 accessions and 99,734 separations entailed in the maintenance and enlargement of a work force of 159,054 employees. This is equivalent to a complete overturn of not less than 63 per cent of the work force during the year. In 1917-18, the most unstable of the periods shown, 631,173 accessions and 613,467 separations, or a total of 1,244,640 labor changes were involved in the maintenance and enlargement of a work force of 305,901 workers. This is equivalent to more than two complete overturns of the work force during the year.

On the basis of the unit full-year (3000-hour) worker the situation in the decade reported may be described as follows: Throughout the ten-year period, for every equivalent 3000-hour worker in the aggregate work force, there were on the average more than two labor changes per year. In 1915, the period of least instability, there were about one and a half labor changes for each full-year worker. In the war period 1917-18 there were more than four labor changes for each full-year worker in the aggregate work force. This is as if during these twelve months all the employees had left their jobs, an entirely new set had come in to fill their places, and afterwards all the employees in this second set had left their jobs and had in turn been fully replaced by a third set of workers.

There is also to be observed in Table 7 a very definite tendency of the mobility rates to vary with the prevailing industrial situation. This tendency is brought out in graphic form in Chart C, on which are plotted the mobility rates shown in Table 7. The influence of the prevailing business and industrial situation is indicated in the chart by the relatively high mobility rates for the years 1913 and 1917-18, years of great industrial activity, and by a recession in the rates in years in which the industrial situation has been less favorable.

CHART C. LABOR MOBILITY RATES BY YEARS, 1910-19  
(Unit: One labor change per full-year worker; Logarithmic scale of ordinates)

Enormous as is the extent of establishment labor instability indicated by these figures, it is fair to assume (and this assumption is supported by a good deal of fragmentary evidence) that the actual situation is even worse. It is especially probable that the labor mobility for the year 1919 is actually higher than is indicated by the figures shown here, since the number of establishments upon which the rates are based is rather small and includes several establishments with unusually low labor mobility records. The (nearly) 500 establishments from which the Bureau of Labor Statistics secured labor mobility figures have necessarily been the concerns which had the figures to give, that is to say, concerns which had given rather more attention than most firms to their force-maintenance problems. The firms reporting are chiefly concerns which had more or less centralized employment systems and were relatively more successful in the maintenance of a stable work force. In such establishments the instability is not likely to be as serious as in the general run of American industrial concerns, which as a rule pay little or no attention to the flow of labor in and out and which give very little thought to its control.

The replacement or turnover numbers and rates in Table 7 are indicated by asterisks.\* This rate of replacement or turnover is, as has already been explained, the rate at which separating employees whose places must be filled are replaced by others. Thus in 1910 persons were being hired at a rate of 1.05 and employees were leaving at a rate of 1.02 per full-year worker. The aggregate standard work force was obviously undergoing expansion, and all separating employees were more or less promptly replaced. The separation rate, therefore, is to be taken as the replacement rate. In 1914 the situation was very different. Most industrial plants were curtailing operations. The result was an accession rate of .81 and a separation rate of .88. In these circumstances it is obvious that not all the separating employees were replaced — even tardily — and that consequently the accession rate is to be taken as the replacement rate. In 1914, obviously, not all of

the 326,755 separating employees contributed to the turnover as that word is here understood. There were only 300,121 persons hired during that year. This number therefore really measures the turnover, because this is the number of abandoned jobs in which there were replacements. The turnover rate, then, is the ratio between 300,121 and the 373,287 equivalent full-year workers who constituted the work force during the time within which those replacements were made. The excess of separations, amounting in 1914 to 26,634, involves a phase of labor mobility not included in turnover. This excess shows the extent to which the normal work force was diminished during 1914 and, in relation to the number of full-year workers, as already explained, it is the labor decrease rate; the corresponding excess of accessions in such a year as 1918 is the labor increase rate. In years like 1911 and 1913 the rates of accession and separation are practically equal, and it would be a matter of indifference which figure were taken to measure replacements. Reference to the actual numbers in the upper part of the table, however, shows that in 1911 the accessions were somewhat less numerous and therefore most nearly measured replacements, whereas in 1913, the separations were fewer and that in that year, therefore, they should be identified with replacements.

It is not believed that the replacement figure is likely to contain non-replacement items. The most important of such items which might be thought to lurk in the replacement figure are those cases of non-replacement brought about by a discontinuance of certain occupations, either because of the shutdown of that part of the plant which includes those occupations, or because of changes in the industrial arts. By definition the replacement rate excludes all such cases, which by the very process of discounting gross separations or accessions to get the replacement rate are automatically eliminated along with other unreplaced separations. This is believed to be true of either an expanding or a contracting business. The margin of error which may result from postponed replacements (in cases where new employees are needed but per-

haps not actually secured for a considerable period after the separation) is not believed to be wide enough seriously to vitiate this method. Moreover, this possible postponed-replacement error is almost always compensatory — replacements not actually made until the end of July for jobs which were abandoned early in June and which should have been accounted for then are, in the long run, balanced by similar delayed replacements carried over from May but actually accounted for in June.

In view of the fact that replacement rates correspond with accession rates when the accession rates are lower than the separation rates, and with separation rates when separation rates are lower than accession rates, it follows that the lowest points on Chart C must mark the rate and trend of labor replacement; that is to say, whichever line happens to be the lowest is the replacement line.

In general throughout the ten-year period the accessions and separations have naturally tended to balance each other pretty closely, although they show slight variations reflecting the changing industrial conditions from year to year. Over the whole decade it is to be noted that the accessions appreciably exceed the separations, indicating a net increase in the gainfully employed population and just about such a normal industrial expansion as would naturally be expected.

During the last few years speculation has been rife as to the probable aggregate number of labor changes over a given period in all the industrial establishments of the country. Interesting though the knowledge of these facts would be, and even if all establishments did keep labor mobility records, the task of gathering such figures would be such a stupendous one that it could scarcely be considered seriously. It is necessary, therefore, to resort to estimates based on a careful analysis of the available labor mobility figures. If, then, the 1919 mobility rates here reported are applied to the factory wage earners in the United

States in that year as shown by the United States Census of Manufactures for 1919, it would appear that the 9,096,372 wage earners on the pay rolls that year must have meant about 8,242,000 accessions, and about 7,703,000 separations, or a total of about 15,945,000 job changes during that year.

#### NECESSARY AND UNNECESSARY LABOR CHANGES

Repeated attempts have been made in the last few years to get at the proportion of the turnover which may be considered to be avoidable. Such a separation of the necessary from the unnecessary replacement has been undertaken on the very natural assumption that the maintenance of the working force requires the hiring of only a certain number of workmen to replace those employees who have left for unavoidable reasons (death, sickness, discharge for manifest unfitness, etc.) and that whatever number of persons is found to be required over and above this so-called irreducible minimum — which has been estimated by a number of students at about 25 per cent of the work force — must be the measure of unnecessary replacement. The limits of this study do not permit a full discussion of the question as to whether or not the data on labor mobility (which phenomenon, as is shown elsewhere, is subject to constant and sometimes extreme fluctuations) can be so simplified as to express in exact figures the proportion of necessary and unnecessary labor replacement. Actually to apply this method of appraising the responsibility in labor replacement to industrial establishments as they are, presupposes wholly static industrial concerns, with unvarying amounts of employment and with work forces composed of persons who are very slightly, if at all, influenced by outside industrial forces. To be sure, there will be found industrial concerns which can offer steady employment to a certain small number of persons. In such establishments any of these employees leaving voluntarily and for no valid reason may be definitely considered as factors in the unnecessary labor replacement. But it would be extremely difficult to say when and to what extent the great

mass of employees (who are at the mercy of labor market fluctuations) may be regarded as contributing to the necessary or unnecessary labor replacement.

Bearing these limitations in mind and assuming that the strictly necessary part of the replacement amounts to 25 per cent

TABLE  
NECESSARY AND UNNECESSARY  
By years, from 1910 to

| YEAR              | NUMBER OF<br>FULL-YEAR<br>WORKERS <sup>1</sup> | LABOR CHANGES NECESSARY TO<br>TAKE CARE OF WORK-FORCE |  |

of the work force (an assumption whose confirmation requires much further investigation), the mobility figures of any firm or group of firms might be presented in such a way to show, separately, the necessary and unnecessary labor replacement. This has been done by applying this correction to the mobility figures shown in Table 7; the resulting figures are presented in Table 8.<sup>1</sup> To show how the extent of the unnecessary labor changes are calculated the following example is cited: According to the fig-

<sup>1</sup> Reprinted from the writers' article on "Mobility of Industrial Labor," 35 *Polit. Sci. Quar.* 584 (Dec. 1920).

ures of Table 7, and assuming as necessary for force maintenance the replacement of 25 per cent of the work force,<sup>1</sup> the maintenance of the aggregate work force of 305,901 employees reported in 1917-18 should have acquired only 76,475 replacements. In addition to these replacements there need to be

considered the persons required to take care of the expansion which the aggregate work force underwent during the period under consideration. The amount of this expansion is measured by the excess of accessions over separations, which is in this case 17,706. The total necessary changes were, there-

<sup>1</sup> And taking for granted, of course, the necessity for whatever increase or decrease changes (accessions or separations, as the case may be) naturally result from the (more or less) permanent extension or curtailment of industrial operations.

<sup>2</sup> Figures taken from Table 7.

<sup>3</sup> Arithmetic difference between accession and separation figures as shown in Table 7.

fore, 76,475 separations requiring replacement, 76,475 accessions for this replacement, and 17,706 labor-increase accessions, or a total of 170,656 necessary labor changes. Actually there were 1,244,640 labor changes. The difference is 1,073,984, which is the number of "unnecessary" labor changes. Computing the rates corresponding to the figures just given, it appears that the accession rate of 2.07 would be reduced to .33, the separation (here the replacement) rate of 2.01 to .24, and the flux rate of 4.08 to .57 if only the strictly necessary labor changes were made.

If the same rate correction be applied to the mobility figures of the period 1913-14, which, unlike 1917-18, was a time of industrial depression, the rate reductions for the earlier period would be as follows: accession (here also the replacement) rate from .93 to .24, separation rate from .99 to .30, flux rate from 1.92 to .54. The figures given in Table 8 show, on the assumption that not more than 25 per cent of the normal work force ought to have been replaced during the year to maintain that force, that most of the job shifting is unnecessary shifting and that this unnecessary shifting is enormous whether the period be one of business expansion or business depression. The percentage of unnecessary labor changes ranges from 54 per cent to 86 per cent of the labor changes which have actually taken place. The proportion of unnecessary labor changes seems to be greatest in periods of marked industrial activity, and in general it seems to fluctuate markedly in response to changes in industrial conditions.

#### LABOR MOBILITY IN CERTAIN LOCALITIES

Attention should be directed to the fact that at identical periods of time there may be considerable variation in the extent of labor mobility in different localities. This will depend upon the extent of industrial activity, and the opportunity for employment for particular kinds of labor in the same locality. It depends, in other words, upon the number of plants in the same locality competing for the same class of labor. It is obvious that many workmen will be attracted to any locality which is known

# GENERAL EXTENT OF LABOR MOBILITY 47

to offer good employment opportunities. Some of these workmen will, of course, prove to be neither stable nor desirable. The labor mobility in the principal cities in which investigations were made is shown in Table 9.

It is evident that Chicago and Detroit, in the 12-month period 1913-14, although it was a period of industrial depression, had mobility rates considerably higher than the average. In the light of the mobility rates for different industries, shown in Table 10, it would seem that, in the case of Detroit, this must be due to the considerable representation of automobile establishments in the figures shown. This industry underwent a remarkable growth during that period and was, relatively, less affected by the industrial depression. In the case of Chicago, it is the figures of the slaughtering and meat-packing industry which boost the mobility rates. In the period of 1917-18 the outstanding facts are the high mobility rates shown for Cleveland, Detroit, and San Francisco. In these three cities the extent of war-manufacturing activities was unusually great and the competition for labor was very keen. In both Cleveland and Detroit the highest mobility was found in the purely industrial establishments which are typical of the two cities, namely, those chiefly engaged in the manufacture of metal products, machinery, automobiles and automobile parts. In San Francisco the unusual labor shifting was most largely due to the enormous war-time expansion of shipbuilding operations on the Pacific Coast and the appeal of the war wages offered to all comers in the shipyards, not only of San Francisco Bay but also of Portland, Tacoma, Seattle, and Los Angeles.

#### LABOR MOBILITY IN DIFFERENT INDUSTRY GROUPS

In Tables 10 *a* and 10 *b* the mobility figures for the two periods, 1913-14 and 1917-18, are classified by industry groups, and the same data are presented in graphic form in Chart D.<sup>1</sup>

<sup>1</sup>Tables and chart reprinted, after recalculation of rates, from "Mobility of labor in American industry," 10 *Mo. Labor Rev.*, 1349-1351.

## GENERAL EXTENT OF LABOR MOBILITY 49

Both the tabular and graphic arrays show the general increase of the mobility rates of the war years over those of the pre-war period and throw interesting side lights upon the influence of the

CHART D. COMPARISON OF LABOR FLUX RATES IN WAR AND PRE-WAR PERIODS  
(Unit: One labor change per full-year worker.)

war upon certain industries. Among the industry groups here represented those which were most immediately affected by the necessity for articles of war are: automobiles and parts, chemical

industries, leather and rubber goods, machinery manufacturing, miscellaneous metal products, and slaughtering and meat packing. All of these groups, with one exception, show a decided increase

in the mobility rates of the war over those of the pre-war period. The rates of the slaughtering and meat-packing group show only a slight decrease. This is not surprising in view of the fact

# GENERAL EXTENT OF LABOR MOBILITY 51

that the mobility rate for this group in 1913-14 was already more than twice as great as the rate for all groups combined.

It might be of interest to recall here the unusual labor situation

10 a

created by the war period and the influence which it had upon labor mobility. War-time necessities forced far-reaching changes in the character of the product manufactured as well as in

the manufacturing processes. Plants producing war materials enormously expanded their operations. The Government itself was forced to expand its own industrial establishments to an unheard-of degree and entered into industrial fields which it had never been in before. The expansion due to war necessities required enormous numbers of work people and made necessary the very rapid training of relatively inexperienced persons who

in many instances were found to be ill adapted to factory work. There was a withdrawal of a very large number of men for military purposes. This military mobilization affected especially those industries which employed males entirely or to a large extent. Women entered into industries in larger numbers and into some industries which had not hitherto employed women. The differentiation of industries into essential and non-essential classes and the promulgation of the "work or fight" order caused large numbers of men employed in non-essential industries to leave their employment and seek jobs in plants carrying on work

essential to the prosecution of the war. Under this ruling inexperienced people, overestimating their capabilities, tried to qualify for experienced men's places and accepted jobs which they soon found out they could not fill.

On account of the unusual industrial expansion during the war period the labor supply became very limited and resulted in keen competition among individual manufacturers. After a time the

competition for labor became so sharp that labor recruiting methods developed which were characterized as being "destructive." The unusual industrial situation created a peculiar war psychology, causing a good deal of restlessness among work people generally. The individual workman, becoming aware of the growing scarcity of labor and of the keen competition for his labor, was naturally quick to take advantage of the favorable employment situation by constantly seeking jobs which would pay more or in which the general conditions of employment were more to his liking.

In respect to the labor situation during the war, the employment manager of a machine-tool manufacturing establishment reports that "Probably the chief cause of labor turnover at this time, particularly among machine tool industries, is the fact that a man tries to go where he can get the highest pay, coupled with the fact that manufacturers are bidding against each other for labor." And he adds that "the second and perhaps equally important cause of turnover in the machine tool trade is the fact that very recently a very large number of men have been forced either by the 'Work or Fight' law or by the necessity of earning larger money to leave the non-mechanical occupations and seek work in machine shops." These men, he says further, "are wholly unfamiliar with our work, have never been accustomed to grease, dirt, and noise, and very naturally find the work somewhat unpleasant. It is quite natural for them to think that the one shop they go to first is probably worse than any other, and if slightly encouraged in this opinion by a smooth-tongued employment man of another shop, they are likely to jump from one place to another, hoping that they will find less grease and dirt."

RELATION BETWEEN SIZE OF ESTABLISHMENT AND LABOR  
MOBILITY "

To undertake to show some definite relationship between the size of the establishment and labor mobility, detailed figures regarding the labor changes were so arranged as to show the mobility rates of establishments with less than a thousand employees, of those having one thousand and under five thousand, and of those with five thousand employees and more. They are shown in Table 11.<sup>1</sup>

These figures in the main indicate a downward trend in mobility rates as the size of the establishment increases. It has not been possible to ascertain the exact reason for the relatively lower rates in the larger establishments, though it is conceivable

<sup>1</sup> See also Table 25, in which quitting, lay-off and discharge rates are shown for different sizes of plant.

that among the factors influencing the stability were the possibility of the larger establishments offering steadier work, relatively higher earnings, and better employment conditions generally. Lower rates might also indicate the efficiency of the

employment department and the influence of service and welfare activities, which are generally carried on more extensively by the larger establishments.

It should also be observed that in the larger establishments there must be many inter-departmental changes which are not.

included in the figures presented here. This is one reason why the flux rate is lower in the large concerns. Obviously the number of such interior labor changes is smaller, both absolutely and relatively, in the small than in the large establishments. The small single-department concern must recruit virtually all its new labor from outside accessions. The inter-departmental labor shift is in some cases quite as much a sign of labor instability as if the shift were from one employing firm to another employing firm.

In connection with the subject of the general extent of labor mobility, brief reference should be made to some particular

phases of the mobility situation having to do with the accession of employees. One of these is the relation of the newly hired employee to labor mobility. How many employees hired within

<sup>1</sup> Reprinted from 35 *Polit. Sci. Quar.* 594.

any particular twelve-month period are still to be found in the firm's employ at the end of that period? An answer to this question is given by the figures presented in Table 12, which shows by industry groups the proportion of the year's recruits who left before they had served a year.

This table furnished a striking illustration of the short periods for which jobs have been held by the newly hired employees during the war period and the rapidity with which they vacate them. Of the 93,206 persons hired during the year ending May 21, 1918, 64,758, or 69 per cent, left before they had served one year. The most stable recruits were those hired by the street railways, only 38 per cent of whom left before serving one year. The most unstable recruits were those hired by miscellaneous metal products manufacturing establishments, 83 per cent of whom left before they had served one year. Two other phases of the accession situation which must be touched upon are the proportion of rehiring among the total accessions, and the relation between the number of applicants and the number of available jobs, on the one hand, and to the number actually hired on the other hand. The number of accessions shown heretofore does not indicate the number of different individuals hired, since the accessions represent the total number of accessions in a given period and include original hirings as well as subsequent rehiring. Figures on the extent of rehiring were obtained by examination of the service records of employees on the pay rolls of six establishments at the end of 1915. They are shown in Table 13.

These figures show that the hiring of 44,166 individuals involved 61,225 hirings and rehiring (repeated transactions), with a resultant increase in the number of accession transactions by nearly 40 per cent. Of the 44,166 individual employees taken on, more than 76 per cent had been hired once only, 15 per cent had been hired twice, over 5 per cent had been hired three times, more than 2 per cent four times, and about one and one-half per cent had been hired and rehired more than five times. Among the employees under observation here the highest

included in the figures presented here. This is one reason why the flux rate is lower in the large concerns. Obviously the number of such interior labor changes is smaller, both absolutely and relatively, in the small than in the large establishments. The small single-department concern must recruit virtually all its new labor from outside accessions. The inter-departmental labor shift is in some cases quite as much a sign of labor instability as if the shift were from one employing firm to another employing firm.

In connection with the subject of the general extent of labor mobility, brief reference should be made to some particular

hired. This means, in other words, that for each person hired for a job there were more than seven persons applying for that job.

The employment manager of a machinery manufacturing establishment reports that in order to obtain 500 employees, during the year ending May 31, 1918, it was necessary to hire at least 1500, only a third of whom showed up ready to go to work on

<sup>1</sup> Based on individual service records of the 13,281 employees on the pay rolls of the three establishments at the end of 1915.

the appointed day. He remarks that the "others apparently were floaters, who drifted from one shop to another and accepted jobs only from the highest bidders. Often when we thought that we had hired a sufficient number of men, we would find the next day that only one or two out of eight or ten showed up to go to work."

## CHAPTER V

### LABOR MOBILITY IN INDIVIDUAL PLANTS AND IN SEPARATE GROUPS WITHIN THE WORK FORCE

IN the figures which have been shown heretofore labor instability was traced largely to seasonal, cyclical, and other fluctuations in industrial activity. It must be pointed out, however, that the extent of labor mobility at any given time is quite different in different industrial establishments, and in different occupations and other groups within those establishments — and this somewhat irrespective of locality and general industrial conditions. Of these many factors which might influence the extent of mobility in individual establishments a few of the more important ones, in so far as they can readily be determined and classified, may briefly be set down here: (1) The particular character of the industry; whether it can offer relatively steady work or whether it is subject to highly seasonal variations in employment. (2) Character of the labor force — that is, the extent to which an establishment employs males and females, unskilled, semi-skilled, or skilled workers; or whether the working force consists largely of clerical employees or of persons engaged in non-mechanical occupations. (3) The general conditions of employment: wages, hours of work, etc.: the particular nature of the work; that is, whether or not it is generally disagreeable and involves exposure to dampness, noxious odors, great heat, dust, etc. (4) The effectiveness of all efforts of the management to overcome purely industrial influences and the more personal desires of individual workmen to change jobs. The influence upon individual establishments and upon special groups within the work force of the various factors enumerated here will be discussed and illustrated in the pages immediately following.

## LABOR MOBILITY IN INDIVIDUAL ESTABLISHMENTS

The mobility rates which have been shown up to this point are group rates in which are merged the individual plant figures of a large number of establishments. They do not indicate the extent of existing variations in the mobility figures of the different establishments making up the group. The forces and conditions determining the extent to which labor changes take place in individual establishments are extremely varied and numerous, as was pointed out above, and they operate differently upon different establishments. Only very exhaustive inquiries could reveal which of many factors involved is particularly responsible for the special virulence or mildness, as the case may be, of instability in particular establishments. The rates in Table 15 register the net general effect which all the factors of influence have had on labor instability in the industrial establishments studied.

In the period 1913-14 the establishment mobility rates are bunched in the lower groups; in the period 1917-18 the rates are less concentrated but more evenly distributed, having quite a large representation even in the high rate groups. Thus the flux rate of 1.92 for the 84 establishments covered in 1913-14 is distributed among 32 per cent of the establishments having a flux rate of 1.20 and under, 26 per cent having a rate of 1.20 to 2.40, 23 per cent a rate of over 2.40 to 3.60, and 19 per cent of the establishments having a flux rate of over 3.60. In the period 1917-18 the flux rate of 176 establishments was 4.08 and there was a corresponding moving up of the establishments into the higher flux rate groups. In that period there were only 3 per cent of the establishments having a flux rate of 1.20 and under, while 16 per cent had a rate of over 1.20 to 2.40, 20 per cent a rate of over 2.40 to 3.60, and 61 per cent a rate of over 3.60. A corresponding movement upward is observable in both the accession and separation rates.

How the sum total of these factors affects the labor instability of the same establishments at different periods and under differ-

ent labor conditions may be seen by comparison of the mobility figures of 20 identical establishments for the two periods 1913-14 and 1917-18. It may be seen from the figures in Table 16 that with the exception of 3 establishments (Nos. 34, 48, and 56) all show a decided increase in the mobility rates over the pre-war period, the rates in one case (Establishment No. 37) being over four times as great in the war as in the pre-war period. For

| Slaughtering and meat packing      | Chicago    | 34 (126)                  | 5,522                           | 8,730   |
| 20 identical firms <sup>2</sup>    | —          | —                         | 61,818                          | 100,708 |

all of the twenty identical establishments taken together, there appears to have taken place nearly a two-fold increase in the flux rate; in 1913-14 it was 2.56, and in 1917-18 it was 4.44, per full-year worker.

It is to be noted, in the figures of Table 16, that in the earlier period the separation rate exceeded the accession rate. Most of these concerns, as was quite generally the case with American industrial establishments at that time, were more or less extensively reducing the number of their employees. In 1917-18, according to these figures, the rate of accession was appreciably

<sup>1</sup> Different mills of this establishment were reported separately in 1917-18, but are here combined for purposes of comparison with 1913-14.

<sup>2</sup> See note 1, p. 65.

| 3.00                                      | 2.19    | 2.73       | 1.83    | 5.73    | 4.02    | Slaughtering and meat pack'g    |
| 1.26                                      | 2.30    | 1.30       | 2.14    | 2.56    | 4.44    | 20 identical firms <sup>1</sup> |

higher than the rate of separation. This reflects, in turn, the industrial activity of the war period. This shift, in a four-year interval, from a contracting, demobilizing industrial machine to an expanding one, is further revealed in the two columns headed "number of full-year workers." The aggregate working personnel of these twenty concerns increased in number from 61,818 in 1913-14 to 109,798 in 1917-18. The figures for the individual establishments show that only four of the twenty firms failed to share in this expansion. Of the four establishments which suffered a decline only one experienced a shrinkage of any considerable proportions.

<sup>1</sup> The rates for the 20 identical firms combined are unweighted arithmetic averages of the respective individual plant rates.

## LABOR MOBILITY OF MALE AND FEMALE EMPLOYEES

The results of a special study of the relative labor mobility among males and females are given in Tables 17 *a* and 17 *b*, which show the labor change numbers and rates for each sex and industry group for the 45 firms reporting the necessary data for 1917-18. In the period covered by the table, female workers made up about one-fourth of the aggregate working personnel of

the forty-five establishments. However, in two of the thirteen industry groups — clothing and textile manufacturing and telephone service — the women far outnumbered the men. It is also to be noted that, in several cases, the number of women workers reported is so small that it is scarcely prudent to attempt generalization. This is especially true where data are shown for only one or two establishments, as, for example, in the case of leather and rubber goods, furniture and millwork and automobiles and parts.

The figures indicate that the mobility rates for females are on the whole considerably lower than for males. It is a rather significant fact that whenever the mobility rates of the males are high the mobility rates of the females are also high. The combined rates of the 45 establishments here studied show the separation rate of the males to be slightly higher than the accession rate, while the accession rate of the females is greater than the separation rate. This is, of course, due to the influx of women into industries during that period. In general, the rates shown here reveal primarily the effect of war-time changes in industry and cannot be said to offer conclusive evidence that shifting is generally less among women. These figures must be used with certain reservations, since the comparison of the mobility between males and females is not made invariably between employees in the same occupation and doing similar work. This is especially noticeable in industry groups in which the female labor force constitutes only a small fraction of the total working force and is composed almost entirely of clerical employees.

#### DAY AND NIGHT FORCE

On the basis of figures secured from a machine tool manufacturing plant the relative responsibility fairly to be assessed against the day and night forces, respectively, for the turnover, can be fairly closely ascertained. In Table 18 the number of labor changes in this establishment and the corresponding rates are given for each year from 1916 to 1919, inclusive.

From these figures it may be seen that, over the 4-year period, 1916-19, the flux rate per full-year worker for the day force was 2.25, that of the night force 6.27, and that of the day and night forces combined 3.06. The mobility of the night force is nearly three times as great as that of the day force and the former is, therefore, responsible for an extent of mobility entirely out of proportion to its strength in the organization. Over the 4-year period the night force constituted about 20 per cent of the total working force, but is chargeable with nearly 45 per cent of the

*LABOR MOBILITY IN INDIVIDUAL PLANTS*      71

total labor changes. The greater shifting among the night workers thus causes the flux rate for the establishment as a whole to be 35 per cent higher than it would be if the changes in the night force were in equal proportion with those of the day force.

## LABOR MOBILITY OF SKILLED AND UNSKILLED EMPLOYEES

Of some interest in the study of turnover is a consideration of the relative instability of the skilled and unskilled. It is generally known that common or unskilled labor is less stable than skilled labor, but extensive figures are not available to show just how much less stable it is. On the basis of figures furnished by a number of industrial plants it is possible to compare skilled and unskilled employees both for the war period and the period immediately preceding the war. The figures are presented in Table 19.

The labor mobility rates for the two classes of labor show that in both periods unskilled labor was much more unstable than skilled labor. Moreover, this excess of instability on the part of the unskilled was much greater in the war than in the pre-war period. In the latter period the mobility rates of the unskilled were more than double the rates for the skilled. In 1917 the mobility rates of the unskilled were three times as great as those of the skilled. In the earlier period there was, among the skilled, slightly more than one labor change for each skilled member of the working force of the twenty-two plants and nearly three changes in unskilled jobs for each unskilled worker. In 1917-18 there were nearly three skilled-labor changes for each skilled worker and about nine unskilled-labor changes for each unskilled worker.<sup>1</sup>

In answer to a question addressed to a large number of establishments regarding the occupation or department in which the labor changes were greatest or least during the war period and the reason why, the almost unanimous opinion expressed was that the greatest shifting was taking place in departments in which the bulk of the employees were classified as common labor. The least shifting was reported to be taking place mainly "among the highly skilled employees who were earning big money and

<sup>1</sup> See also Tables 24 and 39, where additional figures are given on turnover among skilled and unskilled workers.

had long records of continuous service." The extremely large number of labor changes among the unskilled workers was due, it was repeatedly stated, to the fact that during the war period

the demand for common labor was so great that at frequent intervals actual shortages of this kind of help were felt. The ensuing shortages resulted in a sharp competition for common

labor; employers outbid each other in order to obtain it, and the workers, taking advantage of the situation, shifted from plant to plant and city to city in enormous numbers. The competition for help was carried on mainly by means of extensive newspaper advertising. The advertisements were so alluring that, as one large employer put it, "day workers were looking for new positions during the evening and night workers during the day."

#### OCCUPATIONAL INCIDENCE OF LABOR MOBILITY

It is apparent that the mobility rates as shown for an establishment as a whole do not quite accurately reflect the conditions within the establishment, for the reason that the shifting may be largely confined to a single occupation or a group of occupations. To bring out the real significance of the mobility situation, therefore, further classification is necessary. Probably the most significant classification of mobility in individual establishments and one which best brings out the exact responsibility for the labor changes in the working force is that based upon occupations or jobs, or a classification in which the mobility figures are at least kept in relation to certain groups within the working force doing somewhat identical work and having similar working conditions. The advantage of such a classification lies in the fact that it makes it possible to particularize the analysis of existing conditions in the plant and trace the influence upon stability of the nature of the work and the general conditions of employment of each occupation or group of occupations. Table 20 shows the occupational responsibility for labor instability in one of the largest car-building establishments in the United States.<sup>1</sup>

This table shows how greatly the mobility rates of the different occupational groups vary from the rates as a whole. For exam-

<sup>1</sup> It was obviously impracticable to classify the labor changes by distinct operations — of which there were over 700 in this establishment — but the predominant and numerically most important in each department were carefully chosen and are here designated as principal occupations.

ple, the flux rate of the total working force of this establishment is 5.40 while at the same time the rate for one occupation, pattern makers, is 1.05 and for another, riveters, is 11.76. The figures of this establishment also show that, although for the establishment as a whole there has been an excess of separations over accessions, this applies only to some of the occupational groups, while others show the number of accessions to be greater than the number of separations, resulting in corresponding changes in the mobility rates. It is stated by the company that the influence of uncertainty in obtaining materials and certain demoralizing labor conditions are reflected in the high mobility rates of shearsmen, punch-press and power-press operators, bolt makers, and car-body builders. The high shifting frequency of car truck builders and car steam fitters is due to seasonal fluctuations. Assemblers, filers and welders, molders, wood-machine operators and upholsterers show high mobility rates because of the reduction in their number. The highest rates of labor change are found among the riveters and laborers. Both these groups of workers are regarded by the management as being of the floater type, which is a type very difficult to manage. The marked instability of workers in certain occupations in this establishment may be explained by the fact that, during the period for which figures are shown, shipbuilding on the Great Lakes received a great impetus and the type of worker employed in car building could readily be absorbed in shipbuilding plants. The relatively higher wages paid in the shipbuilding industry no doubt attracted many employees from this and other establishments.<sup>1</sup>

<sup>1</sup> See also Table 31, below, where are shown monthly flux rates for the same plant, over the same 12-month period, and for some of the same occupations represented in Table 20.

## CHAPTER VI

### TYPES OF SEPARATION AND CAUSES OF TURNOVER<sup>1</sup>

THE reasons for employees leaving the service of an industrial establishment may be traced back either to purely voluntary action on their part, generally caused by dissatisfaction with the prevailing conditions of employment, or to action initiated by the employer and due either to curtailment of industrial activities or to dissatisfaction with the services of certain of his employees. Separations occurring on the employee's own initiative are referred to in these pages as voluntary separations or quits; and those resulting from the affirmative action of the employer are referred to as lay-offs or discharges, as the circumstances indicate. In attempting to get some conception of the relative responsibility of the various influences bearing upon the mobility of labor it is highly important to give some special consideration to each of these three types of separations. In the figures presented here on the nature of separations, "quits" are taken to include all voluntary separations, including withdrawals due to death, marriage, etc.

Discharges nearly always mean dismissal "for cause," which presupposes some form of incapacity for the work or at least what is believed to be some defect in the character of the employee. Under lay-offs are grouped those who are "let out" either temporarily or permanently whether because of the completion of the job or because of shortage of the particular work at which the laid-off employee was engaged. Lay-offs are not voluntary separations and have nothing to do with the character of the employee. Lay-offs, moreover, seldom are made for a

<sup>1</sup> This chapter reproduced by permission, and with some modification, from the authors' article on "The Causes of Labor Turnover," 2 *Administration*, 649-667 (November, 1921).

definite length of time, and a large proportion of laid-off employees, as a matter of fact, never return to the same establishment from which they were laid off.

In Table 21 are given the number, rate per full-year worker, and the percentage distribution of all separations, of employees discharged, laid off, and leaving voluntarily. Figures are shown for each year from 1910 to 1915 inclusive and for the 12-month period ending May 31, 1918.

The arresting fact shown in the following rate and percentage distribution figures is that the great bulk of all separations to-day, as in 1910, is due to voluntary leaving. It also appears from these figures that periods of industrial prosperity are reflected in relatively low, and periods of depression in relatively high, proportions of lay-offs to total separations, and that the lay-off rate is the most sensitive of the three separation rates to changing industrial conditions. Thus, in 1914, when the ratio of quits to total separations was lower than at any other time during the period covered by the figures, the proportion of lay-offs was higher than at any other time, constituting nearly one third (31 per cent) of all separations, while in the immediately preceding year 1913 lay-offs made up only 7 per cent of all separations. The rate figures indicate that it is not alone the proportion but also the actual rate of lay-off which is thus affected by business activity and depression, the lay-off rate for 1913 being .10, a relatively low figure, and for 1914, .25, per full-year worker, which is an exceedingly high rate for lay-offs.

The discharge rate is evidently subject to less extreme fluctuations than the lay-off rate, and it makes up from year to year a more constant proportion of the total separations. There appears, moreover, to be a rather definite relation between the accession and discharge rates, due, possibly, to the process of selection which goes on when new workers are taken on in large numbers. The consequence of the stimulating effect of business prosperity in boosting the voluntary leaving rates may be seen in the high rates of total separation, in spite of the fact that the

lay-off rates are relatively low. In periods of depression both the rates and the proportions of lay-off and discharge are higher than in periods of prosperity. This is due to the fact that when

depression sets in there are unusually large numbers laid off and employees are discharged more freely than would be the case when labor is urgently needed.

The influence of the prevailing industrial conditions not only upon the separation rate as a whole but more specifically upon the three types of separation — quitting, lay-off, and discharge,

# SEPARATION AND CAUSES OF TURNOVER 81

which make up this rate — is shown in Table 2, on page 16, which gives the trend, from 1912 to 1919, of accession (hiring) and classified separation rates in a middle western metal products

manufacturing plant. This trend, in so far as the separation rates are concerned, is shown graphically in Chart E, on page 83.<sup>1</sup>

Perhaps the most striking fact brought out by this chart is the very close way in which the quitting rate parallels the total

<sup>1</sup> Chart reprinted by permission from the authors' article on "Causes of Labor Turnover," *Administration*, November, 1921.

separation rate, the margin being relatively wide in periods of depression and relatively narrow in periods of great industrial activity. At the points where the separation rate generally declines, the lay-off rate shows, at first, a decided upward trend, but the discharge rate declines even more rapidly than the separation rate as a whole. In the period of increasing industrial activity, especially during the war period, the discharge rate runs along at about the same relatively low level, while the lay-off rate steadily declines, reaching its lowest point at a period which marks the peak of activity in this plant.

The form of the lay-off rate curve in the early part of the seven-year period shows that it was the great increase in the number laid off in the latter part of 1914 that raised the separation rate during that time so considerably above the accession rate. This shows how inaccurate the separation curve would be if taken to measure "turnover" — unless that term is to be used in reference to something entirely different from the amount of change involved in maintenance, that is to say — replacement. Almost the whole margin, in this part of the period, between the separation and accession rates is due to increased lay-offs, i.e., to a (more or less) permanent decrease in the size of the standard working force.<sup>1</sup> Remarkable reductions took place during the first three and a half years, in both the quitting and discharge rates. When the war began in Europe this establishment had, apparently, gone a long way toward the elimination of discharges as a factor in turnover. In the three years from 1912 to 1915, it reduced its rate of discharge from .25 to .05 per full-year worker, or 80 per cent. But during the war period from December 31, 1915, to April 30, 1919, the discharge rate increased 400 per cent. The most important pre-war reduction is, of course, in the quitting rate, because the quitters are responsible for the bulk of the turnover. This company's quitting rate went down from 1.23 in January, 1912, to .36 in June, 1915, — a decline of 71 per cent. But the quitting rate increased 271 per cent between the year

<sup>1</sup> Compare Chart A above, p. 19.

CHART E. TREND OF CLASSIFIED SEPARATION RATES IN A METAL-PRODUCTS MANUFACTURING PLANT, FROM JANUARY, 1912, TO APRIL, 1919  
 (Unit: One separation per full-year worker: Logarithmic scale of ordinates.)

ended December 31, 1915, and the year ended April 30, 1919. It is quite evident, as has been pointed out, that it is the quitting rate which primarily determines the total separation rate.

The disturbing effect of war conditions is very evident. Both accession and separation rates had risen in 1918 to points far above the high points of the 1912-1915 period. An examination of the accession rate and the different separation rates (shown in Table 2) indicates that the war pushed all rates except the lay-off rate well above the remarkably low points reached in 1915. Worse yet, the charts show that it pushed all except the lay-off and discharge rates up to a point even higher than the maximum rates of 1912, so that total separation and accession rates and the replacement rate,<sup>1</sup> which in this case is identical with the separation rate, rose to points never before reached within the period covered by the figures reported. It is interesting to note the effect of the war on the lay-off rate. During the period 1912-1915 it was reduced 28 per cent. War conditions apparently greatly accelerated this reduction and showed a lay-off rate of .08 per full-year worker for the year ended May 31, 1918, as compared with .31 for the year 1915, — a reduction of 77 per cent. But in the latter part of 1918, the lay-off rate began to rise and the rate for the year ending April 30, 1919, stood at .67, the highest it had been since 1915. Despite the increased war demand for labor, the discharge rate increased from .05 in 1915 to .17 in 1918, — an increase of 240 per cent. It has continued to rise, and stood at .25 for the year ended April 30, 1919.

The proportions of the total separations in industrial establishments due to discharge, lay-off, and (voluntary) quitting in the period 1913-14, and to discharge, lay-off, entry into military service, and quitting in 1917-18, are shown in Table 22.

It is evident that the war period brought about a considerable decrease in the proportion of discharges and in the number of establishments having a heavy proportion of separations due to discharges. The war period had the same effect upon lay-offs,

<sup>1</sup> Shown on Chart A, page 19.

but, on the contrary, it brought about a great increase in the number of establishments having a heavy proportion of separations due to voluntary leaving. The figures of Table 22 for sixty-six establishments reporting in 1913-14 and one hundred

| Average . . . . .                                 | .19             | .21         | —                                    | .55                         | .95                      |

How the relative proportions of discharges and voluntary separations have changed during the last few years may be seen from the figures for a large machine tool manufacturing establishment. The percentage of employees leaving voluntarily, as against the total number of separations, for each of the three years ended June 30, 1916, 1917, and 1918, and for the three-months period, July to September, 1918, inclusive, for the day force, were 80, 81, 86, and 92, respectively. The percentages of voluntary separations for the night force, for the same periods, were 77, 82, 91, and 96 per cent, respectively. The ratios of discharged employees for the day force for the years ending June 30, 1916, 1917, and 1918, and the three-months period, July to September, 1918, inclusive, were 20, 19, 14, and 8 per cent, respectively. During the same periods the night force showed the following percentages of discharges: 23, 18, 9, and 5 re-

spectively. Quitting became more frequent; firing much less frequent.

In Tables 23 a and 23 b, the subdivided separation rates are classified according to the various industry groups covered in the two investigations.

These figures bring out some rather important and significant facts with regard to various industries. It is evident, for example, that mercantile establishments had the minimum discharge rate in 1914 and printing and publishing plants in 1918; the minimum lay-off rate in 1914 was in clothing and textiles and in 1918 in printing and publishing; and the minimum quitting rate in 1914 was in the street railway industry and in 1918 in the telephone service. The maximum discharge rate was in the automobile industry in 1914 and in the slaughtering and meat-packing

\* Less than .005.

industry in 1918. The maximum lay-off rate in 1914 was in the automobile industry and in 1918 in mercantile establishments, and the maximum quitting rate was in leather and rubber goods in 1914 and in chemical industries in 1918. The figures show, furthermore, that in 1914 in the automobile group discharges and lay-offs made up over half of all separations, but that by 1918 they had been reduced to less than one-fourth of all separations. In the miscellaneous metal products industries, discharges and lay-offs constituted in 1914 nearly one-third of all separations, but by 1918 they had been cut down to about one-eighth of the total separations. In mercantile establishments, on the other hand, discharges and lay-offs bulk about as heavily among the separations in the earlier as in the later period, making up nearly half of all separations both then and now.

An attempt to establish some relation between the particular type of separation and the relative skill of the separating employee is made in Table 24, in which are classified the returns from 22 establishments which reported mobility figures for skilled and unskilled employees separately.<sup>1</sup>

The degree of occupational training and skill possessed by the employees appears to make little or no difference in the proportion of quits, discharges, and lay-offs in the total number of separations. The percentage distribution figures show that 76 per cent of the skilled employees and 72 per cent of the unskilled employees who left, did so voluntarily; 15 per cent of the skilled and 19 per cent of the unskilled were discharged, and 10 per cent of the skilled and 9 per cent of the unskilled employees leaving were laid off. The situation is quite different, however, with regard to the actual rate of separation, the figures indicating conclusively that the lay-off, discharge, and quitting rates, and, of course, the total separation rate, are each much higher for unskilled than for skilled workers, the total separation rate being

<sup>1</sup> Compare also Tables 19 and 39.

.66 for skilled and 1.41 for unskilled workers. The subdivided separation rates show about the same relation between skilled and unskilled, so that it would appear that skilled workers are about twice as stable as semiskilled and unskilled ones. •

TABLE 24

COMPARISON OF SEPARATION RATES OF SKILLED AND UNSKILLED EMPLOYEES  
LEAVING VOLUNTARILY, DISCHARGED, AND LAID OFF DURING ONE YEAR  
(1913, 1914, and 1915; 22 establishments reporting)

| Quits . . . .    | 12,451                  | 10,003    | .51                                       | 1.03      | 76                         | 72        |
| Discharges . . . | 2,432                   | 4,171     | .09                                       | .27       | 15                         | 19        |
| Lay-offs . . . . | 1,601                   | 1,987     | .06                                       | .12       | 10                         | 9         |

In Table 25 the relation between type of separation and size of establishment is shown on the basis of the mobility figures of the sixty-six establishments reporting in 1913-14 and one hundred and eight establishments reporting in 1917-18.

In the period 1913-14 there is observable quite a marked decrease in the discharge and lay-off rates as the size of the establishment increases. The explanation for this may be sought in the fact that the large-size establishments were less seriously affected by the industrial depression which made itself felt during the latter part of that period. The situation is reversed, however, in the period 1917-18, the discharge and lay-off rates being slightly higher in the larger establishments. In both periods the separation rates as a whole show a slight decrease as the size of the establishment increases.

<sup>1</sup> Based on 74,199,000 skilled-labor hours and 46,980,000 unskilled-labor hours put in during year in the 22 establishments.

## CAUSES OF SEPARATION

The need for definite and detailed information on the causes of labor instability is obvious. In order to devise methods of stabilizing the work force and eliminating unnecessary labor changes, it is quite necessary to know the factors responsible for

the labor shiftings. It is hardly necessary to call attention in this place to the fact that the causes of labor instability present a very vast and complex problem. It is obvious that a determination of these causes, because of their complex nature and the large number of factors to be considered, would necessitate an

inquiry of a magnitude quite beyond the scope of the present inquiry. In discussing the underlying reasons for separations we are disregarding here the separations from service due to purely industrial conditions and fluctuations in production, that is to say, forced separations, or lay-offs, the occurrence of which depends upon whether or not a particular job has been finished or whether or not industrial depression has set in. No attempt is made here to discuss that part of the labor shifting which is due to maladjustment of labor supply and demand caused by an unorganized labor market, by a defective system of labor distribution, or by maladjustment in the matter of wage levels for similar work in different localities, etc.

In view, therefore, of the complexity of the problem and the lack of information on the subject, it is proposed to discuss here, not the causes of mobility that are primarily inherent in the industrial community situation, but the more personal causes of labor shifting as those causes find expression in the separating employee and as they have been classified by individual employers. It is recognized, of course, that the non-industrial and personal causes are inextricably interwoven with the conditions created by the prevailing industrial situation.

In their efforts to stabilize the labor force a number of firms have made attempts to discover the causes of instability and more particularly to find out the immediate, or precipitating, causes for separations from service. They have done this on the assumption that if it were feasible to ascertain the fundamental reasons why men leave their employ, it would be possible, through the tabulation and analysis of those reasons, to show the real causes of instability. It was felt, moreover, that if it were practicable to ascertain the real reasons for employees leaving, it might be then relatively easy to develop a record which would be of considerable value in the solution of the employment problem in the individual establishments concerned, and so point the way toward greater stability.

Even in this individual method of ascertaining the causes for

labor instability there are serious difficulties to be overcome. Employment managers and others in charge of the work force essay to interview an employee who is about to leave of his own accord. This interview is held, of course, before the employee actually severs his connection with the firm. At the interview the employer or his agent tries to secure a frank and truthful statement from the employee regarding the actual reasons which are impelling him to leave. Employers point out, however, the difficulties involved in interviewing prospective quitters. They say that it is difficult to do this, even in normal times, and that it was especially difficult during the war period because of the more independent attitude assumed by the workers. It is generally found that men leaving service do not like to be questioned too closely regarding their reasons for leaving, and often plainly resent such inquiries. It is claimed that in many cases they give some fictitious excuse rather than a substantial reason, and when pressed advance the most plausible reason they can get away with.

From the standpoint of the worker it is perhaps not difficult to understand his reluctance to give full information regarding his reasons for leaving. Such knowledge in the possession of the employer might be disadvantageous to the employee in his search for a new job, and it might in other ways have the effect of restricting his freedom of movement. The employee will have observed that nearly all employment departments keep careful records of employees' past records and that employers generally keep each other informed about the movements of former employees.

To the difficulties of learning from employees the reasons for leaving, there must be added the difficulty of analyzing and classifying the results obtained. It has been the experience of men interviewing prospective quitters that even where the reason for quitting has been obtained, it has not always been easy to reduce to a single classifiable category the manifold motives which may have animated the individual in his desire to change

jobs. Many employment managers believe that only in the case of discharges can the causes of separation really definitely be known. This is obviously because action in the case of discharge proceeds from the management and the employee has nothing to say about it.

For the reasons given in the preceding paragraph, the figures on causes for quitting which are presented below cannot be regarded as more than an indication of existing conditions, although employers who have kept such figures have expressed the opinion that in most cases they point definitely toward certain existing maladjustments and to particular causes that need to be attacked. In Table 26 are given the classified assigned reasons for the voluntary separation and the causes for the discharge of nearly 10,000 employees in six metal trades establishments.

TABLE 26

The classification of causes presented in this table is anything but satisfactory. A more detailed and scientific arrangement was impossible, however, because of the necessity for making a combination of the records of the several establishments, each of which put a somewhat different interpretation upon their recorded reasons for leaving or causes for discharge. Nevertheless, some of the reasons listed can be somewhat more fully explained. Dissatisfaction with wages is evidently the largest single reason for voluntary separation, and no doubt it is safe to assume that the wage motive in one form or another enters into most of the specified reasons for leaving. For those classified under "better jobs" the question of wages is not supposed to have been the prime motive in making the change, but the governing causes for leaving were said to have been more desirable work, the location of the plant, etc. Under "nature of work" are classed a considerable number of quitters who under the stimulus of higher wages or the "work-or-fight" order entered mechanical occupations, but not being accustomed to the grease, dirt, noise, etc., inherent in the nature of the work, constantly have shifted in the hope of finding more pleasant work. It has been stated that the relative ease with which a job could be secured during the war period made workers more ready to throw up jobs which seemed undesirable to them, but which in normal times they would be reluctant to leave.

For those classified under "dissatisfied" no one specific reason seems to have been applicable. Employment managers believe that the question of wages or work is seldom a factor with this type of labor, but that its desire to shift is due largely to an inherent instability and that persons of this type are unable to assign any specific or logical reason for their desire to change. Employment managers believe these considerations to be equally true of a large number of those who failed to report before leaving. It is said that the number of employees leaving in this manner during the war period was greater than at any previous time. This is explained by the fact that the shortage of help necessi-

tated the employment of the so-called "floater," a type of workman which in normal times would not be employed at all by these concerns. It has been found to be characteristic of employees of this sort that they never stay on a job for more than a brief period, soon dropping out, without giving notice, to accept work elsewhere.

Under "incompetent," employment managers have classified certain workers who after a trial have been found to be unfit or unsuited for the work for which they were hired. It was pointed out that although these persons were willing to work they were found to be incapable of learning the work and were responsible for a great deal of spoiled work. This group also included workers who misrepresented their occupational skill when taken on, as, for example, by using certain acquired phrases that would indicate familiarity with the kind of work required of them. The number discharged for incompetency, it is asserted, increased during the war period because the urgent need of men made careful selection less possible. The management has classified those as "unreliable" whose attendance record was bad, who were habitually late in the morning, or who were prone to lay off too frequently and for trivial reasons. A good many of those discharged for being unreliable are suspected by employment managers of having looked for jobs, and possibly of having tried out jobs, in other plants, while absent.

Employment managers have classified as "trouble breeders" those who have attempted to create dissatisfaction among their fellow workers by urging or intimidating them to concerted action of some sort, as, for instance, the unionizing of the shop or the presentation of demands for wage increases, revision of piece or premium rates, etc. The relatively large number discharged for being "trouble breeders" may, perhaps, be explained by the fact that it is the policy of the establishments from which the figures of the above table have been secured to deal with their industrial workers only as individuals.

A somewhat detailed record of the number of people who left

# SEPARATION AND CAUSES OF TURNOVER 99

the employ of a large mail order house during 1917 has been compiled and is presented in Table 27.

TABLE 27

REASONS ADVANCED FOR VOLUNTARY SEPARATION FROM SERVICE OF 13,664 EMPLOYEES AND CAUSES FOR DISCHARGE OF 2849 EMPLOYEES, DURING 1917, IN A MAIL ORDER HOUSE. (ESTABLISHMENT No. 27-109)

| REASONS FOR VOLUNTARY SEPARATION | CASES   |          | CAUSE FOR DISCHARGE    | CASES   |          |

| Distance too great . . .         | 92      | .7       |                        |         |          |
| To go to school . . . .          | 565     | 4.1      |                        |         |          |
| To stay at home . . . .          | 810     | 5.9      |                        |         |          |
| No reason:                       |         |          |                        |         |          |
| Worked less than two             |         |          |                        |         |          |
| weeks; failed to report          | 2,527   | 18.5     |                        |         |          |
| Worked more than two             |         |          |                        |         |          |
| weeks; failed to report          | 1,310   | 9.6      |                        |         |          |
| Total . . . . .                  | 13,664  | 100.0    | Total . . . . .        | 2,849   | 100.0    |

During the year 1917 there occurred in this establishment 22,700 separations. Of this number 5204, or 22.9 per cent, were due to reduction of force and 983, or 4.3 per cent, to entrance into military service. Of the remaining separations, with the causes

of which we are here specifically concerned, 13,664, or 60.2 per cent of all, were voluntary, and 2849, or 12.6 per cent of all, were due to discharge.

It will be seen from the figures of Table 27 that of the total number of voluntary separations, about 25 per cent resulted from employees either having obtained more promising positions or positions which offered higher wages. The number "leaving city" seems to represent a considerable proportion of the total number leaving. It is very doubtful, however, whether this number really left the city; it is quite likely that in the majority of the cases it was only a proffered excuse. Those who were dissatisfied for various reasons number 12.8 per cent of the total. A significant commentary on the whole stability situation in this establishment is implicit in the rather large number of persons who simply dropped out of service without giving any notice of leaving, either in advance or subsequently — nearly 30 per cent of the total number leaving voluntarily left without giving notice.

Among the establishments whose labor turnover experience was examined in some detail by the Bureau of Labor Statistics was one of the largest department stores on the Pacific coast. This store went to no little trouble to ascertain the reasons for employees quitting and to tabulate not only the number quitting for various assigned reasons but also the number discharged for specified cause, assigned, naturally, by the company. This concern also kept account of the proportion of those rehired to new accessions. A full analysis of these records is given in a special report<sup>1</sup> published by the Bureau of Labor Statistics on the turnover experience of this department store. The tabular summary which appears in that report is herewith reproduced, with some modification, in Table 28.

The only classification of the accessions is into "hired new" and "rehired." During the nine months for which data were

Among the establishments whose labor turnover experience was examined in some detail by the Bureau of Labor Statistics was one of the largest department stores on the Pacific coast. This store went to no little trouble to ascertain the reasons for employees quitting and to tabulate not only the number quitting for various assigned reasons but also the number discharged for specified cause, assigned, naturally, by the company. This concern also kept account of the proportion of those rehired to new accessions. A full analysis of these records is given in a special report<sup>1</sup> published by the Bureau of Labor Statistics on the turnover experience of this department store. The tabular summary which appears in that report is herewith reproduced, with some modification, in Table 28.

The only classification of the accessions is into "hired new" and "rehired." During the nine months for which data were

## CHAPTER VII

### SEASONAL INFLUENCE ON LABOR MOBILITY

IN the figures shown in the preceding chapters fluctuations in mobility rates from year to year with changing industrial conditions have been repeatedly observed. While the figures showing the mobility for the year as a whole reflect the sum total of the labor changes that have taken place during the year, they do not indicate the marked fluctuations in mobility at relatively short periods within the year, — fluctuations traceable to the successive vicissitudes of the industrial situation. For example, labor changes may occur with great intensity over a very short period in the year, while over the remainder of the year the changes may be very insignificant. Without showing their seasonal variations, this might make the figures for the years as a whole appear quite low, while actually at the same periods the labor change rates may have been far above the one shown for the year, and at other periods the rates may be considerably lower than the rate shown for the year as a whole.

### SEASONAL AND CYCLICAL FLUCTUATIONS, 1910-19

The figures of Table 29 which show the monthly trend in flux rates from January, 1910, to December, 1919, inclusive, bring out in greater detail the existing variations in the mobility rates and the extent to which mobility figures immediately reflect the industrial conditions prevailing at the time.<sup>1</sup> The flux rate

<sup>1</sup> The figures of Table 29 are based upon following numbers of establishments reporting monthly figures:

|                         |                          |
|-------------------------|--------------------------|
| 1910 — 3 establishments | 1915 — 30 establishments |
| 1911 — 6 “              | 1916 — 10 “              |
| 1912 — 8 “              | 1917 — 20 “              |
| 1913 — 39 “             | 1918 — 19 “              |
| 1914 — 26 “             | 1919 — 9 “               |

figures of Table 29 and, in addition, the corresponding accession and separation rates are shown in Chart F.<sup>1</sup> Since replacement rates, as explained above, correspond with accession rates when the accession rates are lower than the separation rates and with separation rates when separation rates are lower than accession

| December   | 1.11   | 1.14 | 1.89 | 1.26 | 1.23 | 2.31 | 1.74 | 3.54 | 2.40 | 1.20 | 1.80                    |
| Year .     | 3.05   | 1.67 | 2.11 | 2.72 | 1.55 | 1.84 | 2.70 | 3.36 | 3.71 | 2.03 | 2.48                    |

rates, it follows that the lowest points on the chart mark the rate and trend of labor replacement. That is to say, whichever line happens to be the lowest marks replacement.

The monthly flux rate figures in the table show how wide a seasonal range of mobility is covered in each yearly rate. The flux rate was relatively high in 1910, a year of business expansion, but dropped during the depression period of 1911, falling in

<sup>1</sup> Figures for flux curve in Table 29; figures for other curves in Appendix, Table D. The chart has been reproduced, with some modification, from report on labor mobility, 10 *Mo. Labor Rev.* 1358.

<sup>2</sup> Reprinted after shifting of rates to full-year worker base, from report on "Mobility of Labor in American Industry," 10 *Mo. Labor Rev.* 1356 (June, 1920).

CHART F. FLUCTUATIONS IN LABOR MOBILITY, BY MONTHS, FROM JANUARY, 1910, TO DECEMBER, 1919, INCLUSIVE  
 (Unit: One labor change per full-time worker: Logarithmic scale of ordinates.)

December to the low flux (*i.e.* high stability) rate of 1.14, a degree of stability not again reached until the fall of 1914, in November of which year of business depression it fell to 1.11. The flux rate rose generally in 1912 and 1913, but dropped toward the end of 1913 and remained low during 1914 and until the fall of 1915, when it rose slightly, followed by a further rise and continued high mobility levels during the winter and spring of 1916. The summer and fall of 1916 and the winter of 1917 were periods of greater stability. In the late spring of 1917, after our entry into the war, the labor flux rate jumped to higher points than it had touched since the spring of 1913. There was — and this is an unusual circumstance — only a very slight increase in mobility during the following summer, fall, and winter. With the spring of 1918 the rate climbed again, and this time to high points not reached at any other time before or since, during the decade covered by the figures. The rate fell considerably during the summer and fall of 1918, and, despite the almost invariable tendency to rise in the spring, it continued low during the winter of 1919 and gradually fell during the spring, rising somewhat in the fall, but dropping sharply in November and December.

An examination of the chart will show that the very unusual decrease in mobility in the spring of 1919 was largely due to the fact that in addition to a marked decrease in the separation rate (unusual at this time of year) there was an even more pronounced drop in the accession rate. It is evident, also, that in the fall of 1919 the accession rate rose rapidly until October, and then dropped rapidly, while the separation rate continued to drop through the summer and fall.

#### SEASONAL FLUCTUATIONS IN INDIVIDUAL ESTABLISHMENTS

The seasonal fluctuations in labor mobility as they occur in a machine tool manufacturing plant are shown in Table 30, on page 107. The figures show for the four-year period 1916-19 not only the monthly trend in the flux, for the work force as a whole, but also the monthly trend for the same period for the day and

# SEASONAL INFLUENCE ON LABOR MOBILITY 107

night forces separately. Attention has been called above, in the discussion of Table 18, to the fact that the night force in this establishment is nearly three times as mobile as the day force. Table 30 naturally shows up the same difference in

TABLE 30

| December .  | 1.26  | 2.37 | .72  | 1.26 | 2.76        | 5.40 | 1.77 | 3.33 | 1.53                | 3.03 | .87  | 1.77 |
| Total .     | 2.73  | 2.34 | 2.49 | 1.35 | 7.11        | 7.11 | 5.70 | 4.59 | 3.72                | 3.27 | 3.18 | 1.83 |

stability and demonstrates, furthermore, that, except in March, 1919, there was no month during the whole four-year period that did not show greater stability for the day force.

## SEASONAL CHANGES AMONG DIFFERENT OCCUPATIONS

The figures given in the last two tables refer to the monthly trend in the mobility rates of the general body of employees without reference to seasonal fluctuations of given occupations within the work force. In one of the large car-building plants (Establishment No. 102) employment records were kept in such form that the monthly labor flux rates of some of the more

| Upholsterers                                | 3.39  | 5.16                             | 2.49  | 5.13  | 2.58  | 2.70  |
| Wood machine operators                      | 5.10  | 5.16                             | 2.76  | 5.31  | 3.09  | 6.54  |

important occupations within the plant could be computed. The rates are shown in Table 31 above.

The flux rates given here not only show very wide differences between the different occupations, but reveal even more marked fluctuations from month to month in each occupation. The highest flux rates and at the same time the widest range of rates during the year ending May 31, 1918, were for riveters, whose rates ranged from 18.96 in June down to 5.85 in December, with a flux rate for the year of 11.76, which means nearly 12 labor changes for every riveter in the standard work force of riveters — changes equivalent to six complete overturns of the riveting

personnel. The next highest flux level and the next widest range from month to month occurred among common laborers, whose flux rate ranged from 14.40 in April down to 7.35 in July, with a flux rate for the year of 10.80, — this being equivalent to 5½ complete overturns of the common labor section of the work force. The lowest occupational flux rate in the plant was for inside car trimmers, in whose case the flux rate ranged from .57 in October to 3.33 in February, with a rate of 1.74 for the year, a rate equivalent to less than one complete overturn of the inside car-trimming section of the work force. In most of the occupations shown the mobility rates are generally low during the winter

months as compared with the rates for the year. In these monthly figures of the mobility of occupations one may see how the various factors of influence previously mentioned are immediately reflected in the mobility figures from month to month.<sup>1</sup>

#### NORMAL SEASONAL CHANGES IN STABILITY

A composite picture of the seasonal fluctuations in labor mobility over an extended period of time can be constructed from the monthly mobility rates for the period 1910-1919. Such a picture will naturally iron out the irregularities due to business fluctuations from year to year and show what may be called the normal seasonal trend in labor mobility. The figures are presented in Tables 32 and 33 where the monthly figures (shown in Table D in the Appendix) for each month of each year of the decade covered are brought together in such a way as to combine the figures for identical months (Table 32) and for the four seasons of the year (Table 33). The rate figures of Table 32 are presented graphically in Chart G, on page 112.

It is believed, as already suggested, that such a combination of the figures as is shown in these two tables effectively neutralizes most of those factors in mobility which are of a purely industrial character and that, as a result, the influence of the different seasons is more accurately reflected. The figures indicate a uniform tendency to maximum labor mobility in the spring, a gradual lessening of mobility during the summer and early fall, which is the period of minimum mobility, and finally an increase during the late fall and winter, culminating again in the maximum mobility period of the following spring. These conclusions are confirmed by the curves of Chart G. The high mobility rates in the spring months indicate that the shiftings are indeed much more numerous at that season of the year. The number of

<sup>1</sup> See also Table 20 above, where mobility rates for some of the same occupation groups given in Table 31 are shown for this same establishment for the year as a whole.

# SEASONAL INFLUENCE ON LABOR MOBILITY III

accessions and separations in the months of March, April, and May are not only greatest in relation to the number of workers employed, but in themselves are greater in this three-month period than in any other period shown. Here, doubtless, may be seen the psychological effect which spring appears to have

TABLE 32

| June, July, August . . |  |                               | 1.29                      | 1.26        | 2.55         |
| Sept., Oct., Nov. . .  |  |                               | 1.19                      | 1.00        | 2.19         |
| Dec., Jan., Feb. . .   |  |                               | 1.21                      | 1.03        | 2.24         |
| Total . . . .          |  |                               | 1.31                      | 1.17        | 2.48         |

tions of living are more easily met. The relatively high mobility rates still prevailing during the summer months no doubt indicate the influence of the hot weather upon the industrial stability of the employee. In the fall of the year when colder weather sets in and living conditions are harder to meet, there is a noticeable drop in the labor change rate as a whole. It is especially interest-

<sup>1</sup> Reprinted, after shifting rates to full-year-worker base, from report on labor mobility, 10 *Mo. Labor Rev.* 1356 (June, 1920).

<sup>2</sup> The figures are obtained in this way:  $\frac{353,803,000}{3000}$ .

ing to note that the proportion of accessions as compared with the proportion of separations is relatively greater during the months of September, October, and November, indicating a tendency for workers to flock back to steadier employment after a period of restlessness and moving about. There is also noticeable a very slight increase in the mobility rates of the winter months over the fall period, which is perhaps indicative, on the one hand, of a more intensive application of the country's productive forces, and on the other, of changes which are often made by individuals at the end of the old and the beginning of the new year.

## CHAPTER VIII

### LENGTH OF SERVICE AS A FACTOR IN LABOR MOBILITY

IN the preceding discussion of labor mobility one very important factor, that of length of service, has been only briefly touched upon in connection with an analysis of accessions.<sup>1</sup> Monthly and yearly figures expressed in the form of accession, separation, and flux rates are valuable for the purpose of showing the general extent of mobility in the labor force as a whole and its trend during any given period of time. Such figures, however, do not throw much light on the degree of stability within the working force, in so far as it relates to the length of service of the active as well as the separated employees, without which no correct idea can be formed of the relative extent of labor mobility. It is evident that in the working force as a whole, or in its sex, occupation, or other subdivisions, the turnover is not equally distributed, because of the varying frequency with which the jobs in each such group may be abandoned by the job holders. It is obvious that the length of time for which jobs are held by individual employees who leave those jobs, is a highly important factor in determining the incidence of labor mobility within the establishment work force. This is for the reason that the shorter the service of separated employees, the more frequent the job replacements which they occasion, and the higher the resulting establishment labor mobility figures.

Moreover, from the standpoint of an individual establishment eager to maintain an esprit de corps in the plant, and for that reason bent upon minimizing its labor changes, the length of service of its employees becomes an all-important factor. In

<sup>1</sup> See Table 12. Further applications of the length of service data are made in Chapters IX and X.

order to guarantee that team-work which is essential in modern factory production, and which is the result of long association of the same groups of workmen, effort must be made to prevent employees of long standing from leaving the employ of the concern. The retention in service of long-service employees is especially important from the standpoint of the cost of replacement, as it is generally agreed that as the length of service of the employee increases, his value to the organization is also enhanced. If, however, the severance of connection of an employee becomes unavoidable, it is of importance to retain — assuming that he proves to be desirable — the newly hired employee who is taken on to replace the one who has left. This is also true of those employees hired to enlarge the working force. It is quite obvious that there must be a heavy expense attached to the constant breaking in of new employees. This expense is enormous, even without considering the cost of spoiled work, decreased production, and industrial accidents which inevitably follow as a result of this everlasting shifting.

The experience of 34 establishments in 1913-14 and 53 in 1917-18 which furnished comprehensive figures on the length of service of their active employees as well as of those who left their employ, is summarized in Table 34, on page 117.

If we consider those employees having to their credit not more than one year of service as short-service employees, it will be noticed in this table that the proportion of such employees in the active work force is rather extensive. On the other hand, considerable proportions among the active employees are found to have long-service records. This proportion of long-service employees in industrial establishments was considerably reduced during the war period, slightly over 71 per cent of those on the pay roll in 1913-14 having had over one year's continuous service, while in 1917-18 the proportion was only 60 per cent. There are, of course, wide variations in the extent to which individual establishments have short- and long-service employees in the active working force. Space limitations, however, make

TABLE 34

LENGTH-OF-SERVICE DISTRIBUTION OF "ACTIVE EMPLOYEES" (THOSE ON PAY ROLL AT END OF YEAR) AND OF EMPLOYEES WHO LEFT DURING THE YEAR ("SEPARATING EMPLOYEES")<sup>1</sup>

[Number of establishments reporting, 1913-14, 34; 1917-18, 53]

| LENGTH-OF-SERVICE GROUP             | NUMBER IN EACH GROUP       |         |                                    |         |

it impossible to present length of service data by individual establishments.

As might be expected, the length-of-service figures of the separated employees present a striking contrast to those shown

<sup>1</sup> Reprinted from report on labor mobility, 10 *Mo. Labor Rev.* 1357 (June, 1920).

for the active working forces. This undoubtedly reflects the influence of unusual industrial activity in both of the periods studied, but more especially the effect of war-time conditions upon labor mobility. It is apparent from the figures of Table 34

TABLE  
LENGTH OF SERVICE OF EMPLOYEES ON PAY ROLL AT END OF YEAR ("ACTIVE

tinuous service records from one to five years, and 32.9 per cent with service records of over five years, and figures for 1917-18 show 32.9 per cent of all active employees with service records of over one to five years and 27.8 per cent with continuous service records of over five years.

A count of the actual length of service of 439 separated employees in two establishments in the one-week-or-less group showed the number of employees having had specified days of service to be as follows: Less than one day of service, 21 employees; one day, 94 employees; 2 days, 57 employees; 6 days, 111 employees. This shows that over 25 per cent worked one day or less, about 80 per cent worked from two to five days, and only a little over 25 per cent worked a full week.

The results of a separate study of the relative proportions of active and separated employees who had served specified periods of time are shown by industry groups in Tables 35 *a* and 35 *b*.

In both periods rather marked variations may be observed in the relative proportions, in the different industry groups, of those in service at the end of the year and those separated during the year. The extent to which any industry group has long-service employees in the active work force will depend, of course, on the seasonal character of the industry, whether the work force has recently been extended, whether the plant has reduced its force by lay-off of those most recently hired, or on all of these factors combined. In the first two cases there will very probably be found a relatively smaller proportion of long-service employees, while in the last case the number of employees of long tenure will be relatively larger. In the case of the active employees, the influx of new workers during the war period due to enlarged industrial activities may be seen in the proportion of those having short-service records in 1917-18 as compared with 1913-14. In both periods employees of long tenure are found to a greater or less extent in all industry groups shown, the proportion of employees with over 5 years' service being in some cases almost one-half the total active working force. However, the

enormous shifting of workers which took place during the war period, especially in war industries, is strikingly illustrated by the figures for separated employees. It will be observed that some industry groups show as high a proportion as 80 per cent of all the separated employees to have worked three months or less. The proportion of separated employees who had served one week or less appears to have been in some industry groups as high as from 60 to 80 per cent. A considerable number of long-service employees were lost to the different establishments during the war period, as may be seen from the rather large proportions of long-time employees who left the service in some industry groups.

#### COMPARATIVE SERVICE STABILITY OF MALES AND FEMALES

The figures shown in Tables 36, 37 and 38 are the result of a special study of the relative importance of the length of service as a factor in labor mobility in industrial establishments as between males and females. Table 36 summarizes for the war period the experience of 28 establishments in that regard. The figures of this table are presented graphically in Chart H on page 125. Table 36 shows the proportions of the males and females in the working force to be about equally divided in the lower length of service groups, the females having higher proportions in the service groups between six months and five years, but showing a much greater proportion of males in the over-five-years group. A comparison of the length of service of the separated male and female employees shows that larger proportions of separating male employees than females are bunched in the short-service periods. Thus, 63 per cent of the total number of separating males as against 50 per cent of the females had served less than three months. In the groups over-six-months-to-a-year the proportions are about equally divided. In the long-time-service groups of separated employees the figures for males show that they are less prone to sever connections with an establishment after having worked in it a consider-

able period of time. Of all the separating females whose service records were reported, 18.7 per cent had served over one to five years, whereas only 11.3 per cent of all the separating males

TABLE 36

<sup>a</sup> Includes 1 establishment with 328 males reported as having served "over 5 to 10 years."

<sup>b</sup> Includes 1 establishment with 655 females reported as having served "over 5 to 10 years."

The influence of the war period upon the length of service of males and females is brought out in Table 37. The figures are based upon the identical length of service distribution of the males and females in the active working forces of 30 establishments in 1914, and 28 establishments in 1918. It is evident that the proportion of short-service employees, both for males and females, is considerably greater in the war than in the pre-war period. In 1913-14 it appears that 27.5 per cent of the males and 27.4 per cent of the females of the active work force had service records of one year or less; the corresponding figures for the war period are 37.2 and 40.4 per cent, for males and females, respectively. The proportion of long-service employees in the active working force — and this applies to both males and females — decreased during the war period, as may be seen from the records of the number who had over one year's continuous service. In 1913-14 the figures show that 72.5 per cent of the males and 72.6 per cent of the females were in service for over one year. In 1917-18 the proportion of the males who served more than one year decreased to 62.8 per cent and the corresponding proportion of the females to 59.6 per cent.

The summarized figures of the length-of-service distribution of 28 establishments in 1917-18 classified by sex as shown in Table 36 are given in greater detail in Tables 38 *a* and 38 *b* which show, by industry groups, the length of service of active and separated male and female employees.

The figures presented in these tables show pronounced variations in the different industry groups in the proportion of male and female employees who had served given periods of time. This irregularity is apparent among both active and separating employees. It will be noted, however, that, in many cases, there are, within the same industry group, only slight differences in the proportions of males and females having identical length of service. Yet in certain service groups there are evident rather wide differences. Such discrepancies are noticeable in the over-five-years group, where male workers appear in much the larger proportions.

group who left during the year.

a Less than 0.5 per cent.

## LENGTH OF SERVICE OF SKILLED AND UNSKILLED

The relation between the degree of skill and the length of service of both active and separated employees was made the subject of a special inquiry reporting the experience of 17 establishments covering the years 1913, 1914 and 1915. The results are shown in Table 39.

TABLE 39

LENGTH-OF-SERVICE DISTRIBUTION OF "ACTIVE EMPLOYEES" (I.E., THOSE ON PAY ROLL AT END OF YEAR) AND OF EMPLOYEES WHO LEFT DURING THE YEAR ("SEPARATED EMPLOYEES"), CLASSIFIED ACCORDING TO SKILL, 1913-1915

| Total . . . . .                   | 100.0   | 100.0     | 100.0  | 100.0     |

The figures indicate that only about one-tenth of the skilled employees on the pay roll, but nearly one-fourth of the unskilled,

had served as short a time as three months or less. The proportions of the skilled and unskilled active employees who had served from one to five years are about the same; in the over-five-years service group of active employees there is a considerable difference, however, the proportion of skilled in that group being 33.3 per cent, whereas the proportion of unskilled is only 16.6 per cent. Among the separated employees it is only in the long service groups that there is any decided difference in the relative proportions of skilled and unskilled employees, the unskilled separating employees showing a slightly higher percentage in the length-of-service groups of one year or less, the figures being 81.7 per cent for skilled and 86.7 per cent for unskilled. In the over-one-to-five-year groups the proportion of separated skilled employees is 14.5 per cent, and that of the unskilled 11.6 per cent; in the over-five-years group the skilled represented 3.9 per cent and the unskilled 1.7 per cent of the total separations.<sup>1</sup>

In the discussion of the relative mobility of the skilled and unskilled workers, attention has been directed to the fact that there was more frequent shifting among the unskilled workers generally, as compared with the skilled, and that this shifting of the unskilled has taken on enormous proportions during later years.<sup>2</sup> The mobility records of individual workmen are of no little interest in this connection. In 1914, Mr. P. A. Speek, an investigator for the Commission on Industrial Relations, made a very thorough and painstaking first-hand study of the unskilled migratory worker. In his report to the Commission, Mr. Speek includes as an appendix the "copies of record cards of 7 typical floating laborers applying at the State Free Employment Office, Milwaukee, Wisconsin (in the period 1911-1913), showing the number and nature of jobs during certain periods of time." These records show in chronological order the nature of the various jobs held, with the dates on which the laborers were sent to those jobs. A summary of the records follows:

<sup>1</sup> See also Tables 19, 24, and 49.

<sup>2</sup> See Table 19.

1. Patrick J. Flynn, 87 jobs during 23 months and 6 days, or one job in every 8 days.
2. Jos. Stein, 7 jobs during 5 months and 4 days, or one job in every 22 days.<sup>†</sup>
3. Frank O'Neill, 16 jobs during 7 months and 10 days, or one job in every 14 days.
4. Matt Brewer, 20 jobs during 10 months and 19 days, or one job in every 16 days.
5. Chas. Sommer, 72 jobs during 10 months and 19 days, or one job in every 4½ days.
6. Fred Miller, 59 jobs during 6 months and 8 days, or one job in every 3½ days.
7. William Thompson, 34 jobs during 12 months and 14 days, or one job in every 11 days.<sup>1</sup>

A very interesting side-light upon the shifting of common laborers during the war period and the duration of their employment on different jobs is furnished by the record of one of the large printing establishments in the Middle West shown in Table 40, on page 135.

For a period of three months this firm kept a record of the length of service of unskilled male laborers who left their employ. Besides recording the length of time jobs have been held, the age, wage rate received, and finally, the reason for leaving of each individual worker, are also given. The period under consideration marks one of enormous expansion in industrial activity, and the competition for labor, especially for common labor, was exceedingly keen during the period under observation. The influence of these factors upon the situation is very clearly reflected in the data shown in this table. Of the 78 individual laborers listed 37 worked less than a week, 11 worked a full week, 10 worked between 10 days and 3 weeks, and only 20 worked more than a month before they quit. It does not appear that either the age or wage rate influenced stability to any appreciable extent one way or another. Men of all age groups and of both

higher and lower hourly wage rates are found among those employees who served only a few days as well as among those who had served longer periods. Half of the workers listed left without giving any reason or giving any notice of their intention to leave. A large proportion left because they found the work either too hot or too hard; only a few of those who quit indicated that they had other jobs in view.

LENGTH OF SERVICE IN DIFFERENT PLANT DEPARTMENTS

Just as the labor instability is not distributed in equal degree among the different sections of the work force, so the length of service of the active employees as well as the employees leaving differs widely in different sections of the work force. This is well illustrated in Table 41.

TABLE 41

LENGTH-OF-SERVICE DISTRIBUTION OF "ACTIVE EMPLOYEES" (I.E., THOSE ON PAY ROLL AT END OF YEAR), AND OF EMPLOYEES WHO LEFT DURING THE YEAR ("SEPARATED EMPLOYEES"), IN A MEN'S CLOTHING-MANUFACTURING PLANT (ESTABLISHMENT NO. 103), 1917-18

The proportion of short-service employees in the active working force is greatest in the "general" department — where 20.4 per cent of those in service at that time had served 3 months or less. In the tailoring department the corresponding length-of-service group has 9 per cent, and in the cutting and trimming departments 6 per cent, of the employees on the pay roll. This firm, known for its liberality in dealing with labor, is able to show a proportion of long-service groups well above that of the ordinary run of establishments. The proportion of employees with service records of over one year is 57.7 per cent, 70.9 per cent and 82.8 per cent, respectively, in the three departments named. Turning to the separating employees, it is evident that the cutting and trimming department lost fewer of its old-time employees than the other two groups, although a good deal of shifting also took place in these latter departments, as is indicated by the large proportion of employees who left employment after short periods of service.

#### AVERAGE WEEKLY SERVICE RATES

It is a matter of course that as the period of service increases the number of employees who have served such period decreases — and decreases usually at a progressively increasing rate. This naturally holds true for both active and separating groups of employees. The length-of-service figures presented in the preceding pages do not reveal this tendency, for the reason that the length-of-service records were not tabulated on a scale made up of equal intervals of time. In Table 34, for example, it appears that nearly as many separated employees had service records falling within a range of from one to seven days as had service records of from one to three months — in which group the range is about nine times as great. This statement of the situation is true, but misleading. The really significant difference is that between the number of quitters who had worked one week or less and the average weekly number of quitters into which the total number who had worked from one to three

months is distributed. The comparison should be between weekly averages of active and separated employees in the different tenure groups. In other words, the important thing to know is not so much the number leaving who had one to three months' service records as the number of quitters assignable on the average to each of the nine weeks of the one to three months' period — what may for the sake of brevity be called the average weekly number leaving (or working on the active force) in each classified service period.

#### LENGTH OF SERVICE AND TYPE OF SEPARATION<sup>1</sup>

This "weekly average" is made the basis of Table 42 which shows the number, per cent distribution, and corrected (i.e., weekly average) separation service rates per full-year worker, of employees quitting voluntarily, laid off, and discharged from 30 establishments reporting for the pre-war period.<sup>2</sup>

In this table the declining scales of corrected rates indicate much more accurately than do the unsubdivided figures the relative importance of long and short time employees as factors in the turnover situation. Relatively high average weekly (i.e., corrected) separation rates, particularly in the shorter time periods, indicate relatively low stability — that is to say, high turnover. Thus it is evident from the corrected separation rates of Table 42 that in every service period the frequency of quitting voluntarily is from 3 to 7 times as rapid as the frequency of lay-off separation and from 2 to 5 times as rapid as the frequency of discharge. For all three types of separation by far the heaviest responsibility falls on the under-3-months group in which employees leave, whatever the circumstances of their separation, 4 and 5 times as rapidly as they do in the 3-to-6-months group. In the latter group, in turn, they leave almost twice as rapidly as in the 6-to-9-months group; taking the extreme ends of

<sup>1</sup> See Chapter VI for discussion of type of separation without reference to length of service.

| Over 6 to 9 months . . . . .  | 1 | Over 3 to 5 years . . . . . | 8 |
| Over 9 months to 1 year . . . | 1 |                             |   |

<sup>2</sup> Less than .0005.

the service scale it appears that employees leave voluntarily and are laid off or discharged at least one hundred times as rapidly from the under-3-months as they are from the 3-to-5-years group. The percentage distribution figures indicate that in each service group, quits, lay-offs, and discharges make up roughly the same proportion of the total separations assignable to each service group, quits ranging from 58 to 72 per cent, lay-offs from 10 to 20 per cent, and discharges from 18 to 26 per cent.

## CHAPTER IX

### STABLE AND UNSTABLE EMPLOYEES

IN the discussion of the figures on the length of service of the active working force attention has been called to the fact that in each establishment at a given time there will, of course, be found a certain proportion of long-service employees. No matter what divisions of the working force may be considered — shifts, departments, the skilled and unskilled, distinct occupations, etc. and whatever the prevailing factors may be that influence the rate of labor mobility of these groups — they all will be found to contain elements of stability. Inordinate shifting of labor is characteristic only of certain parts of the working force. This of course, does not mean that senior employees do not sooner or later also change their employment and that they are not to be reckoned at all as a factor in labor mobility. But in each establishment at a given time will be found a nucleus of workers who have become a part of the permanent working force, who have grown up in the establishment, as it were, and who are for various reasons less desirous of change. The fact that it is only a portion of the working force which becomes a factor in the labor mobility over a given period shows that there is more or less concentration in the mobility of the plant force, and for that reason the rates of mobility as applied to the working force as a whole do not correctly assign the direct responsibility for the labor flux. It is evident that the rates of mobility would be the same if the whole working force changes completely once in the course of a year, or, if one-half of the work force changes two times, or, one-fourth of the work force changes four times, in the course of a year, and so on. In the presentation of the figures that follow an attempt is made to establish a more simple and direct connection between length of service and labor mobility.

The detailed period-of-service figures of active employees in the industry groups shown in Table 35 in seven length-of-service divisions, have been condensed in Table 43 into just two divisions; those who have served continuously for periods up to one year and those who have continuous service records of over one year. The same figures are shown graphically in Chart I.

TABLE 43  
NUMBER AND PER CENT DISTRIBUTION OF "ACTIVE EMPLOYEES" WHO HAD SERVED ONE YEAR OR LESS AND OVER ONE YEAR, RESPECTIVELY, IN SPECIFIED INDUSTRY GROUPS, 1917-18. (53 ESTABLISHMENTS)

| INDUSTRY GROUP                                  | NUMBER           |               | PER CENT         |               |

| Machinery manufacturing . . . . .               | 6,760            | 11,504        | 37.0             | 63.0          |
| Mercantile establishments . . . . .             | 625              | 826           | 43.0             | 57.0          |
| Miscellaneous metal products mfg. . . . .       | 2,750            | 3,410         | 45.0             | 55.0          |
| Printing and publishing . . . . .               | 231              | 709           | 25.0             | 75.0          |
| Public utilities. Gas and electricity . . . . . | 864              | 977           | 47.0             | 53.0          |
| Street railways . . . . .                       | 1,908            | 2,300         | 45.0             | 55.0          |
| Telephone service . . . . .                     | 5,667            | 12,811        | 31.0             | 69.0          |
| Total . . . . .                                 | 28,448           | 43,321        | 40.0             | 60.0          |

It is at once evident that of 71,769 persons on the pay rolls of the 53 establishments on June 1, 1918, 43,321 or 60 per cent had been in continuous service over one year. These long-service employees were in no way responsible for the labor mobility of these establishments for the 12-month period ending with that date. The proportion of employees who were free from responsibility for the labor shifting depends upon the proportion of long-service employees in the working force, which, as may be seen, varies considerably between the industry groups shown, the highest percentage of employees having service records of over

CHART I. PROPORTION OF "ACTIVE" EMPLOYEES WHO HAD SERVED ONE YEAR OR LESS AND OVER ONE YEAR, RESPECTIVELY; BY INDUSTRY GROUPS

one year being in printing and publishing. Generally, the proportion of over-one-year active-service employees is greater than the proportion of active employees who have worked less than one year. There are two exceptions among the industry groups: automobiles and parts manufacturing and chemical industries and refineries. In these two groups the proportion of active employees with service periods of less than one year is greater than those with over one year's service.

Knowing the number of employees with service records at least as long or longer than the period for which the labor mobility is reported, the responsibility of that part of the working force which has actually occasioned the labor instability can be definitely established, and in Table 44 the base upon which the rate of mobility is measured is that part of the work force which directly contributed to it. The rate figures given in the table are plotted on Chart J on page 148. The table and graph show the responsibility for labor mobility of the stable and unstable employees, respectively.<sup>1</sup>

It will be observed that in these 53 establishments with a working force of 69,553 there were at the end of the year 43,321 employees, representing 62 per cent of those on the pay roll, with a service record of over one year. These employees were not responsible for any of the labor changes that took place during the year. The labor mobility is thus concentrated on 26,232 workers or 38 per cent of the total work force. This relatively small part of the work force was responsible for the labor changes which took place during the year, involving 93,206 accessions and 96,207 separations, a labor flux of 189,413 persons. This means that for every worker on the unstable work force more than 3 persons were hired and nearly 4 persons left employment, involving altogether more than 7 labor changes for each worker. A comparison of the labor mobility of the stable and unstable working force shows the labor mobility rates based

<sup>1</sup> For detailed figures regarding stable and unstable employees in individual establishments see Table C in the Appendix.

<sup>1</sup> This number is 2216 less than the number on the pay roll of the 53 establishments at the end service having been reduced to equivalent full year, or 3000 hour, workers.

<sup>2</sup> Represents ratio of labor changes (accessions, separations and flux) to labor hours of total working

<sup>3</sup> Represents ratio of labor changes (accessions, separations and flux) to labor hours of unstable part of the working force.

<sup>1</sup> This number is 2216 less than the number on the pay roll of the 53 establishments at the end service having been reduced to equivalent full year, or 3000 hour, workers.

<sup>2</sup> Represents ratio of labor changes (accessions, separations and flux) to labor hours of total working

<sup>3</sup> Represents ratio of labor changes (accessions, separations and flux) to labor hours of unstable part of the working force.

proportion of long-service employees in the different establishments.

The importance of employees of long tenure as a factor in labor stability and their influence upon labor mobility rates is well illustrated by the mobility figures for the telephone service group. At the termination of the mobility census it appeared that 74 per cent of the employees had been in service more than a year, thus concentrating the labor mobility upon 26 per cent of the total work force. The labor change rates in the telephone service as applied to the total working force are .90, 1.05 and 1.95 for accession, separation, and flux, respectively, but the number of labor shiftings when applied to that part of the working force to which the turnover is actually attributable show corresponding rates of 3.39, 3.96 and 7.35. This clearly indicates relatively low labor mobility for the working force as a whole in the telephone service, reveals a concentration of whatever labor mobility there has been upon a comparatively small portion of the plant forces and shows very frequent changes within the personnel of the unstable labor group.

In general, it may be observed that in those industry groups which have a comparatively low percentage of unstable employees and also a relatively low mobility rate as based upon the total working force, the difference between the mobility rate based on the total working force and the rate based on the unstable working force is also considerably greater than in industry groups in which a larger proportion of the working force is responsible for the mobility. The explanation for this is that in those industry groups which show a low percentage of unstable employees only a comparatively small part of the work force is responsible for the labor changes, and the labor forces of these industry groups contain a large number of senior employees who are not at all responsible for the flux. These establishments for that reason are able to show a comparatively low mobility rate when based on the entire working force. In establishments showing a higher percentage of unstable employees the responsibility for

the labor shifting is more evenly distributed in the working force, and differences in the mobility rates between the stable and unstable working force are, therefore, correspondingly lower. For example, the unstable working force in the telephone service group is relatively small — 26 per cent; the difference in the flux rates between the stable and unstable working force is 5.40. In the automobiles-and-parts group the unstable working force is comparatively large — 53 per cent — and the difference in the flux rate of the two divisions of the work force is only 2.61.

Because of the great variations in the mobility rates of the individual establishments constituting any particular industrial group, some summary figures classifying the labor flux rates of the stable and unstable working force of the 53 individual establishments covered in the preceding table are given below.

TABLE 45

| Over 1.2 to 2.4 . . . . .    | 14   | —                      |
| Over 2.4 to 3.6 . . . . .    | 18   | 2                      |
| Over 3.6 to 4.8 . . . . .    | 6  | 4                      |
| Over 4.8 to 6.0 . . . . .    | 8  | 9                      |
| Over 6.0 to 7.2 . . . . .    | 4  | 13                     |
| Over 7.2 to 8.4 . . . . .    | 2  | 6                      |
| Over 8.4 to 9.6 . . . . .    | —  | 6                      |
| Over 9.6 to 10.8 . . . . .   | —  | 5                      |
| Over 10.8 to 12.0 . . . . .  | —  | 2                      |
| Over 12.0 to 13.2 . . . . .  | —  | 1                      |
| Over 13.2 to 14.4 . . . . .  | —  | 3                      |
| Over 14.4 to 15.6 . . . . .  | —  | 2                      |
| Total . . . . .              | 53   | 53                     |

The great range of variation in the flux rates of the unstable working forces of the 53 individual establishments (the combined rate for which is 7.2) may be gauged from the fact that the unstable-work-force flux rate in two establishments falls so low as to come within the flux-rate group of over 2.4 to 3.6 (about two changes for each worker in the unstable work force), while there are two concerns the flux rate of which is classified in the flux-rate group of over 14.4 to 15.6 (about 15 labor changes for every employee in the unstable work force). An even more striking presentation of the comparative instability of stable and unstable employees is made in Table 46. In it the data relating to the labor mobility of the individual establishments are grouped according to the relative proportions of their unstable employees to the total working force.

These figures bring out in a very graphic manner the fact to which reference has been made above; namely, that as the proportion of the unstable working force increases, thus showing the responsibility for the labor changes to be more largely distributed among the whole working force, the labor mobility rates also show a decided tendency to increase. The margin, however, between the labor change rates of the whole work force and those of the unstable working force is decidedly less as the proportion of the unstable portion of the working force to the total working forces increases. A comparison of the flux rates of the two divisions of the working force shows this margin to be as follows: when the proportion of unstable working force to total working force is 20 per cent or less, the flux rate margin is 6.63; when it is over 20 to 40 per cent, the margin is 4.26; when it is over 40 to 60 per cent, the margin is 3.96; and when it is over 60 per cent, the margin is 1.92.

TABLE

COMPARISON OF LABOR MOBILITY RATES BASED ON THE TOTAL WORKING FORCE, CLASSIFIED ACCORDING TO THE RELATIVE SIZE OF

| ESTABLISHMENTS IN WHICH PROPORTIONS OF UNSTABLE WORKING FORCE TO TOTAL WORKING FORCE WERE — | NUMBER OF ESTABLISHMENTS | TOTAL WORKING FORCE | UNSTABLE PART OF WORKING FORCE | LABOR HOURS                     |

## CHAPTER X

### RELATIVE RESPONSIBILITY OF DIFFERENT SERVICE GROUPS FOR LABOR MOBILITY

THE length-of-service figures given in Chapter VIII, although useful for some purposes, fail to report the true situation as to the proportion of the whole amount of shifting for which each different length-of-service group of separating employees must be held responsible. The principal difficulty with such a length-of-service classification as that shown in Table 34 is that the service periods in the scale are of unequal length and the numbers of those leaving during those unequal periods are, therefore, not strictly comparable. It is true that a revision was made in the last table presented in the chapter on length of service,<sup>1</sup> in which table the unequal time periods are equated by dividing the figures of each group by the number of weeks in the span of service time. This method, however, is not quite adequate, and in Table 47 the same set of length-of-service figures is so presented as to make in another and more accurate way the necessary correction for this disparity in length between the different service periods.<sup>2</sup>

The first column of the table is identical, except for decimals, with the corresponding figures for the active employees in Table 34. In column 2 the total number of labor hours worked by the employees of the fifty-three concerns in 1913-14 and the corresponding number worked by the employees of the thirty-four concerns in 1917-18, respectively, are distributed (for each of the two periods) in the same percentage proportions that hold for the employees who were on the pay roll at the end of the year.

<sup>1</sup> Table 42, p. 140.

<sup>2</sup> The method used in Table 47 was suggested to the writers by Mr. Lucian W. Chaney, of the U. S. Bureau of Labor Statistics

| Over 2 years to 3 years . . . . . | 9.23  | 19,259  | 2,476                      | .39   |
| Over 3 years to 5 years . . . . . | 8.81  | 18,383  | 2,780                      | .45   |
| Over 5 years . . . . .            | 27.75   | 57,993  | 3,015                      | .16   |
| Total . . . . .                   | 100.00  | 208,659 <sup>2</sup>  | 93,092                     | 1.34  |

<sup>1</sup> Calculated after this fashion:

$$\frac{28,407}{293,51000} \times 3000 = 2.90.$$

<sup>2</sup> Aggregate number of labor hours worked, during the years covered, in the establishments represented in the table, for the war and pre-war periods respectively.

This reveals the number of full-year workers assignable to the various length of service groups. Column 3 is identical with the separation figures in Table 34. In column 4 are given the rates of separation per 3000 labor hours worked by each length of service group. These figures are obtained by dividing the number of separating employees who have served each specified time period by the number of labor hours worked by that group and multiplying the quotient by 3000. The resulting scale of separation rates gives a very good idea of the relative responsibility of the different service groups for excessive labor mobility and shows that the great bulk of it is caused by the short-time employee, very little of it, indeed, being due to the separation from service of employees who had served more than one year.

The separation rates for each of the different industry groups, presented in Table 48, are derived in exactly the same way as are the rates in the last column of Table 47.

TABLE  
SEPARATION RATES IN SPECIFIED INDUSTRY GROUPS, CLASSIFIED ACCORDING TO  
AMONG THE DIFFERENT LENGTH-OF-SERVICE

| INDUSTRY GROUP                     | RATE OF SEPARATION PER FULL-YEAR WORKER IN EACH |                                 |                                  |                                 |                                |                                |
|------------------------------------|---|---------------------------------|----------------------------------|---------------------------------|--------------------------------|--------------------------------|

| Public utilities:                  |   |                                 |                                  |                                 |                                |                                |
| Gas and electricity . . .          | 1.23  | .69                             | 1.95                             | 1.23                            | .60                            | .48                            |
| Street railways . . .              | 4.80  | 2.55                            | 2.64                             | 2.07                            | 1.38                           | 1.23                           |
| Tel. service . . .                 | 9.39  | 5.49                            | 4.83                             | 2.64                            | 2.19                           | .93                            |
| All industries . . .               | 10.53   | 5.56                            | 4.04                             | 2.76                            | 2.02                           | 1.12                           |

Again, in Table 48, the rapidly declining separation rate figures along the length-of-service scale show how relatively little the long-service employees have to do with the labor shift. Some significant differences between the industry groups may be pointed out: In street railways and telephone service, two similar groups whose total separation rates are about equal, there is, nevertheless, a wide difference between the corresponding rates in the shortest service group. This would seem to indicate, as has been suggested in another chapter, that the telephone service industry is obliged to make much more frequent replacements of employees who have served less than a week than is the case with street railways. A similar disproportionately high separation rate among those who have worked less than a week is observable in the clothing and textile manufacturing group, which has for this minimum service period the highest rate of all the groups shown, and this despite the fact that the total separation rate for this industry group is slightly below the average.

48

LENGTH OF SERVICE. (BASED ON ALLOCATION OF THE TOTAL LABOR HOURS GROUPS). 1917-18 (53 establishments)

<sup>1</sup> See, for other statistical data on skilled and unskilled workers, Tables 19, 24, and 39.

<sup>2</sup> Obtained by dividing the number of separations in each group by corresponding number of labor hours and multiplying by 3000.

# FREQUENCY OF JOB REPLACEMENT IN DIFFERENT LENGTH-OF-SERVICE GROUPS

It has already been pointed out that, as is quite obvious, there is enormous variation in the turnover distribution in relation directly to length of service, that the jobs held by the newly hired employees — whether they are skilled mechanics' jobs or unskilled laborers' jobs — are responsible for a preponderating share of the separations. For some jobs there is evidently a very

TABLE 50

RELATIVE FREQUENCY OF JOB REPLACEMENT IN SPECIFIED LENGTH-OF-SERVICE GROUPS. 1917-1918

(53 establishments reporting)

high "rotation in office"; for others the frequency of shift is much lower. It is very important to know what proportion of the jobs in a plant is subject to high, and what proportion to low, rotation frequencies. An attempt to indicate this is made in Table 50 above, which presents a further analysis of the service distribution of 78,176 persons who, before they had

This same analysis of the length of service data is followed in Table 49, which makes a comparison between skilled workers and semi-skilled or unskilled workers. The figures again exhibit a difference in stability in favor of skilled workers.<sup>1</sup>

<sup>1</sup> See, for other statistical data on skilled and unskilled workers, Tables 19, 24, and 39.

<sup>2</sup> Obtained by dividing the number of separations in each group by corresponding number of labor hours and multiplying by 3000.

is possibly two days rather than four. This probable lag of the true average of individual cases behind the mean length of service which has been used is undoubtedly greatest in the one-week-and-under group and certainly cannot be of any serious consequence in the longer groups. In any case the effect of this probable lag or negative deviation is to produce a somewhat lower turnover figure. Thus, if two days be taken as the basic average for the first group, there would appear in this rapidly changing part of the working force a group of 90 jobs, in each of which there were 90 replacements during one year, whereas, on the four days' basis it is a group of 180 jobs, each having 90 replacements annually. In short, the mean length of service is, especially for the very short periods, more nearly an outside figure for, rather than an average of, the individual cases.

It should be noted also that the calculation is based upon the calendar year of 365 days and not upon the number of days worked by a "fully employed person," which latter basis is used in other parts of this book in computing the number of full-time jobs or standard working force.

This method of working out the results in Table 50 may be illustrated by the figures for the first group. On the basis of the assumption explained above, each of 16,476 persons worked an average of 4 days. Assuming that all jobs were continuously occupied, it follows that the number of successive incumbents of each job subject to this maximum frequency of "rotation in office" must have been 365 divided by 4, or 91.3. Similarly there must have been 33.2 persons in successive occupancy of each of the jobs held by the one-to-two-weeks group, and so on. This constitutes a series of constants, supplementing the mean-length-of-service constants in column 4 and indicating the average number of men required during the year to hold down each job in each of the specified time groups. The next step is to ascertain the number of jobs, each of which is successively occupied by 91 employees, 33 employees, etc., during the year. This is done by dividing the number of man-days worked in each group

(the product of the mean length of service by the number of employees in the group) by 365. This indicates that in the one-week-and-under group there are 181 jobs, to each of which an average job replacement frequency rate of 91 incumbents per year applies. Similarly in the over-one-to-two-weeks group there are 291 jobs (2 per cent of all the full-time jobs) in which there are 32 replacements a year; and at the other end of the scale, in the 6-months-to-one-year group, 7366, or 46 per cent of all full-time jobs, in which there are  $1\frac{1}{3}$  replacements a year. The figures indicate, in other words, the numbers of full-time jobs in which there were the classified numbers of incumbents per year. They mean, e.g., that on the average each of the 181 full-time jobs in the first and shortest group had 91 incumbents during the year.

At the relatively stable end of the length-of-service scale it appears that the six-months-to-one-year group, numbering 9813, who had occupied 7366, or 46 per cent, of the full-time jobs, contributed 13 per cent of the separations and suffered one replacement a year. At the unstable end of the scale it is evident that the under-one-week group, numbering 16,476 employees, who had occupied 181, or 1 per cent of the full-time jobs, contributed 21 per cent of the separations and suffered 90 replacements a year. In this most unstable group, where the jobs naturally suffer the highest replacement frequency, it would appear that in each of 181 full-time jobs there were, on the average, 90 new men hired, and this little group of jobs was occupied at one time or another during the year by 16,476 persons, who made up 21 per cent of the separations and, consequently, were responsible for that proportion of the turnover. It is realized that these conclusions are based upon the estimated figures for the mean length of service in each time period. This makes it impossible in every case to check the derived figures of Table 50 with the direct figures reported from the establishments, but does not appear to invalidate the general conclusion.

## CHAPTER XI

### EMPLOYMENT RECORDS

THE establishment employment records primarily needed for the development of useful statistics of labor mobility on the lines indicated in the body of this book are:

- (1) Number of labor hours worked,
  - a.* In the shape of clock records or other records of labor, time, or
  - b.* To be derived from daily attendance records, or
  - c.* From amounts paid out in wages at various rates,
  - d.* From pay-roll records by some method of discounting gross pay roll for both absentee-time and fractional-pay-period time.
- (2) Number of accessions.
- (3) Number of separations,
  - a.* Number leaving voluntarily,
  - b.* Number laid off,
  - c.* Number discharged.

For the convenient recording of the above items some such record-form as the one on pages 164-165 is suggested.

The information called for in Form 1 should be recorded daily. The daily record can, of course, be kept on the same form, if the column at the right be left blank for insertion of the time unit desired. The figures should, if possible, be shown separately by plant occupations or operating departments. The daily records for any division, or for the plant as a whole, can, at the end of the month, be totaled and entered on the monthly record shown here. This monthly record, in turn, can be totaled and entered, at the end of the year on a corresponding form showing the annual mobility record for each department.

## LABOR TURNOVER IN INDUSTRY

FORM 1: LABOR  
OCCUPATION OR

| January . . . . .                  |   |                                       |   |                    |            |          |
| February . . . . .                 |   |                                       |   |                    |            |          |
| March . . . . .                    |   |                                       |   |                    |            |          |
| April . . . . .                    |   |                                       |   |                    |            |          |
| May . . . . .                      |   |                                       |   |                    |            |          |
| June . . . . .                     |   |                                       |   |                    |            |          |
| July . . . . .                     |   |                                       |   |                    |            |          |
| August . . . . .                   |   |                                       |   |                    |            |          |
| September . . . . .                |   |                                       |   |                    |            |          |
| October . . . . .                  |   |                                       |   |                    |            |          |
| November . . . . .                 |   |                                       |   |                    |            |          |
| December . . . . .                 |   |                                       |   |                    |            |          |
| Year . . . . .                     |   |                                       |   |                    |            |          |

The figures for "size of work force" are of prime importance, but, except for ordinary pay-roll data, they are kept by very few employers — and even when such figures are kept they are not usually put in the same record with data on number of employees entering and leaving, with the result that it is very difficult to get all factors upon a common footing for purposes of computation. Method (1) is believed to be the best of the three. The first alternative to this actual number of labor hours is the average daily number actually at work. These attendance figures may be converted to labor hours by first multiplying by the number of days worked and then by the number of hours in the regular work-day and, finally, subtracting, from the resulting gross number of labor hours a number of hours considered to be equivalent to the time lost through the absenteeism of active

|                     |       |   |           |            |            |                      |       | November                           |               |
|                     |       |   |           |            |            |                      |       | December                           |               |
|                     |       |   |           |            |            |                      |       | Year                               |               |

employees and the time not worked by employees who failed to work the full pay period. The second alternative to actual labor hours is the average number of employees on the pay roll. These figures may be converted to labor hours by multiplying them by the number of days worked during the month, and that product in turn by the prevailing number of hours worked per day during the month or other period considered.

Length-of-service figures are very important, especially in reference to the employees who leave. For each separating employee a record should be kept of the time of his continuous service and entered monthly, or as often as considered desirable, on some such form as the one shown on pages 166-167.

The scale of time periods shown above is that used in the more recent of the two labor mobility investigations made by the

| All departments . . . . .         |                                |                         |                                  |                          |                          |

Bureau of Labor Statistics. Somewhat different classifications may be found more useful for some concerns, but, whatever scale is used, it should be split up into very short time periods for the first weeks and months of service time. The number serving less than one week should by all means be shown in the records, for the great bulk of the labor shift will fall in these very short periods.

The foregoing items represent the most important data necessary for keeping a constant check on the extent of labor mobility and the progress being made in different departments toward controlling it. Whatever forms are used should be so flexible that they can be adapted to specialized treatment of a problem and be made to serve for any desired period. It is recommended that the following records should certainly be kept:

A daily record of men hired and transferred, giving name, number, department, job, and rate of pay. A record of all men

leaving, giving the date hired and date leaving, type of separation, length of service, either the actual time in years, months, or days, or giving it in definite classified periods. Such a record has the advantage that it is possible to combine the figures for any department for any job or for any desired period.

### ABSENTEE RECORDS

Some record should be kept of absentees. This is especially important for establishments where it is found to be necessary to compute the mobility rates on the basis of pay-roll figures which will need to be discounted for the amount of absenteeism. The form on pages 168-169 is suggested for absentee records.

Absentee records will fall under two major divisions: daily and monthly. Each of these must contain both quantitative and qualitative information. The quantitative data show, not only the number of employees absent, but also the number of hours

lost. Thus an employee absent forty days, with a broken leg should count as one case, but in his record there should also be shown the equivalent labor hours involved in forty days' absent.

The qualitative data analyze causes of absenteeism. The

## NOTES TO TABLE A

° Unless it is otherwise specified, the figures for 1913-14 refer to the year ended June 30, 1914, and the figures for 1917-18 refer to the year ended May 31, 1918.

\* Figures in parentheses are the 1917-18 numbers of such concerns as were reported in 1917-18 as well as 1913-14.

† Each of the two mills which constitute this establishment was reported as a separate concern in 1917-18.

a. This group of plants reported in a special article, "Labor Turnover in Chicago," 9 *Monthly Labor Review*, 652-667 (September, 1919).

b. This group of plants reported in a special article, "Labor Turnover in Cincinnati," 8 *Monthly Labor Review*, 651-668 (March, 1919).

c. This group of plants, together with those in Detroit, reported in a special article, "Labor Turnover in Cleveland and Detroit," 8 *Monthly Labor Review*, 11-30 (January, 1919).

d. This concern reported in detail in a special article, "Labor Turnover and Employment Policies of a Large Motor Vehicle Manufacturing Establishment," 7 *Monthly Labor Review*, 837-855 (October, 1918).

e. The figures shown here are based upon the records of five individual establishments. They were secured in connection with another investigation carried on simultaneously in the cloak and suit industry of Cleveland. The results of this investigation were published in the *Monthly Labor Review* for August, 1918.

f. This group of plants reported in a special article, "Labor Turnover in Milwaukee," 8 *Monthly Labor Review*, 909-1016 (April, 1919).

g. This group of plants reported in a special article, "Labor Turnover in the San Francisco Bay Region," 8 *Monthly Labor Review*, 303-380 (February, 1919).

h. This concern reported, with another oil refinery, in detail in a special article, "Labor Policies and Labor Turnover in the California Oil Refining Industry," 8 *Monthly Labor Review*, 969-998 (April, 1919).

i. This concern reported in detail in a special article, "Employment Policies and Labor Mobility in a California Sugar Refinery," 9 *Monthly Labor Review*, 1802-1824 (December, 1919).

- <sup>1</sup> Calendar year 1913.
- <sup>2</sup> Not including special employees averaging 181 during the year.
- <sup>3</sup> Including student operators.
- <sup>4</sup> For nine months' period ended September 30, 1914.
- <sup>5</sup> Calendar year 1915.
- <sup>6</sup> Year ended November 30, 1914.
- <sup>7</sup> Year ended October 31, 1915.
- <sup>8</sup> Calendar year 1912.
- <sup>9</sup> Year ended June 30, 1918.
- <sup>10</sup> Six months' period ended June 30, 1918.
- <sup>11</sup> Year ended April 30, 1918.
- <sup>12</sup> Ten months' period ended June 30, 1918.
- <sup>13</sup> Eight months' period ended June 30, 1918.
- <sup>14</sup> Figures cover conductors and motormen only.
- <sup>15</sup> Year ended March 31, 1918.
- <sup>16</sup> Ten months' period ended May 31, 1918.
- <sup>17</sup> Eight months' period ended May 31, 1918.
- <sup>18</sup> Six months' period ended July 31, 1918.
- <sup>19</sup> Period from August 20, 1917, to July 7, 1918, inclusive.
- <sup>20</sup> Six months' period ended May 31, 1918.
- <sup>21</sup> Seven months' period ended May 31, 1918.
- <sup>22</sup> Nine months' period ended May 31, 1918.
- <sup>23</sup> Year ended July 31, 1918.
- <sup>24</sup> Year ended January 31, 1918.
- <sup>25</sup> For 9  $\frac{1}{4}$  months ended August 12, 1918.
- <sup>26</sup> For 8  $\frac{1}{4}$  months ended August 15, 1918.
- <sup>27</sup> Eight months' period ended August 31, 1918.
- <sup>28</sup> For 7  $\frac{1}{4}$  months ended August 15, 1918.
- <sup>29</sup> Six months period ended August 31, 1918.
- <sup>30</sup> Year ended August 31, 1918.
- <sup>31</sup> Not including employees hired in one department, which had about 125 employees.
- <sup>32</sup> Six months' period ended June 26, 1918.
- <sup>33</sup> Year ended May 15, 1918.
- <sup>34</sup> Year ended May 2, 1918.
- <sup>35</sup> Year ended October 31, 1918.
